# About This Manual

## **Subject**

This manual describes QAnywhere, which is a messaging platform for mobile and wireless clients as well as traditional desktop and laptop clients.

## **Audience**

This manual is for users of SQL Anywhere and other relational database systems who want to add messaging to their mobile applications, or who want to build new mobile application-to-application messaging solutions.

## SQL Anywhere documentation

This book is part of the SQL Anywhere documentation set. This section describes the books in the documentation set and how you can use them.

### The SQL Anywhere documentation

The complete SQL Anywhere documentation is available in two forms: an online form that combines all books, and as separate PDF files for each book. Both forms of the documentation contain identical information and consist of the following books:

- ◆ **SQL Anywhere 10 - Introduction** This book introduces SQL Anywhere 10—a comprehensive package that provides data management and data exchange, enabling the rapid development of database-powered applications for server, desktop, mobile, and remote office environments.
- ◆ **SQL Anywhere 10 - Changes and Upgrading** This book describes new features in SQL Anywhere 10 and in previous versions of the software.
- ◆ **SQL Anywhere Server - Database Administration** This book covers material related to running, managing, and configuring SQL Anywhere databases. It describes database connections, the database server, database files, security, backup procedures, security, and replication with Replication Server, as well as administration utilities and options.
- ◆ **SQL Anywhere Server - SQL Usage** This book describes how to design and create databases; how to import, export, and modify data; how to retrieve data; and how to build stored procedures and triggers.
- ◆ **SQL Anywhere Server - SQL Reference** This book provides a complete reference for the SQL language used by SQL Anywhere. It also describes the SQL Anywhere system views and procedures.
- ◆ **SQL Anywhere Server - Programming** This book describes how to build and deploy database applications using the C, C++, and Java programming languages, as well as Visual Studio .NET. Users of tools such as Visual Basic and PowerBuilder can use the programming interfaces provided by those tools.
- ◆ **SQL Anywhere 10 - Error Messages** This book provides a complete listing of SQL Anywhere error messages together with diagnostic information.
- ◆ **MobiLink - Getting Started** This manual introduces MobiLink, a session-based relational-database synchronization system. MobiLink technology allows two-way replication and is well suited to mobile computing environments.
- ◆ **MobiLink - Server Administration** This manual describes how to set up and administer MobiLink applications.
- ◆ **MobiLink - Client Administration** This manual describes how to set up, configure, and synchronize MobiLink clients. MobiLink clients can be SQL Anywhere or UltraLite databases.
- ◆ **MobiLink - Server-Initiated Synchronization** This manual describes MobiLink server-initiated synchronization, a feature of MobiLink that allows you to initiate synchronization or other remote actions from the consolidated database.

- ◆ **QAnywhere** This manual describes QAnywhere, which defines a messaging platform for mobile and wireless clients as well as traditional desktop and laptop clients.
- ◆ **SQL Remote** This book describes the SQL Remote data replication system for mobile computing, which enables sharing of data between a SQL Anywhere consolidated database and many SQL Anywhere remote databases using an indirect link such as email or file transfer.
- ◆ **SQL Anywhere 10 - Context-Sensitive Help** This manual provides context-sensitive help for the Connect dialog, the Query Editor, the MobiLink Monitor, the SQL Anywhere Console utility, the Index Consultant, and Interactive SQL.
- ◆ **UltraLite - Database Management and Reference** This manual introduces the UltraLite database system for small devices.
- ◆ **UltraLite - AppForge Programming** This manual describes UltraLite for AppForge. With UltraLite for AppForge you can develop and deploy database applications to handheld, mobile, or embedded devices, running Palm OS, Symbian OS, or Windows CE.
- ◆ **UltraLite - .NET Programming** This manual describes UltraLite.NET. With UltraLite.NET you can develop and deploy database applications to computers, or handheld, mobile, or embedded devices.
- ◆ **UltraLite - M-Business Anywhere Programming** This manual describes UltraLite for M-Business Anywhere. With UltraLite for M-Business Anywhere you can develop and deploy web-based database applications to handheld, mobile, or embedded devices, running Palm OS, Windows CE, or Windows XP.
- ◆ **UltraLite - C and C++ Programming** This manual describes UltraLite C and C++ programming interfaces. With UltraLite you can develop and deploy database applications to handheld, mobile, or embedded devices.

## Documentation formats

SQL Anywhere provides documentation in the following formats:

- ◆ **Online documentation** The online documentation contains the complete SQL Anywhere documentation, including the books and the context-sensitive help for SQL Anywhere tools. The online documentation is updated with each maintenance release of the product, and is the most complete and up-to-date source of documentation.

To access the online documentation on Windows operating systems, choose Start ► Programs ► SQL Anywhere 10 ► Online Books. You can navigate the online documentation using the HTML Help table of contents, index, and search facility in the left pane, as well as using the links and menus in the right pane.

To access the online documentation on Unix operating systems, see the HTML documentation under your SQL Anywhere installation or on your installation CD.

- ◆ **PDF files** The complete set of SQL Anywhere books is provided as a set of Adobe Portable Document Format (pdf) files, viewable with Adobe Reader.

On Windows, the PDF books are accessible from the online books via the PDF link at the top of each page, or from the Windows Start menu (Start ► Programs ► SQL Anywhere 10 ► Online Books - PDF Format).

On Unix, the PDF books are accessible on your installation CD.

## Documentation conventions

This section lists the typographic and graphical conventions used in this documentation.

### Syntax conventions

The following conventions are used in the SQL syntax descriptions:

- ◆ **Keywords** All SQL keywords appear in uppercase, like the words ALTER TABLE in the following example:

```
ALTER TABLE [ owner.]table-name
```

- ◆ **Placeholders** Items that must be replaced with appropriate identifiers or expressions are shown like the words *owner* and *table-name* in the following example:

```
ALTER TABLE [ owner.]table-name
```

- ◆ **Repeating items** Lists of repeating items are shown with an element of the list followed by an ellipsis (three dots), like *column-constraint* in the following example:

```
ADD column-definition [ column-constraint, ... ]
```

One or more list elements are allowed. In this example, if more than one is specified, they must be separated by commas.

- ◆ **Optional portions** Optional portions of a statement are enclosed by square brackets.

```
RELEASE SAVEPOINT [ savepoint-name ]
```

These square brackets indicate that the *savepoint-name* is optional. The square brackets should not be typed.

- ◆ **Options** When none or only one of a list of items can be chosen, vertical bars separate the items and the list is enclosed in square brackets.

```
[ ASC | DESC ]
```

For example, you can choose one of ASC, DESC, or neither. The square brackets should not be typed.

- ◆ **Alternatives** When precisely one of the options must be chosen, the alternatives are enclosed in curly braces and a bar is used to separate the options.

```
[ QUOTES { ON | OFF } ]
```

If the QUOTES option is used, one of ON or OFF must be provided. The brackets and braces should not be typed.

## File name conventions

The documentation generally adopts Windows conventions when describing operating-system dependent tasks and features such as paths and file names. In most cases, there is a simple transformation to the syntax used on other operating systems.

- ◆ **Directories and path names** The documentation typically lists directory paths using Windows conventions, including colons for drives and backslashes as a directory separator. For example,

```
MobiLink\redirector
```

On Unix, Linux, and Mac OS X, you should use forward slashes instead. For example,

```
MobiLink/redirector
```

- ◆ **Executable files** The documentation shows executable file names using Windows conventions, with the suffix *.exe*. On Unix, Linux, and Mac OS X, executable file names have no suffix. On NetWare, executable file names use the suffix *.nlm*.

For example, on Windows, the network database server is *dbsrv10.exe*. On Unix, Linux, and Mac OS X, it is *dbsrv10*. On NetWare, it is *dbsrv10.nlm*.

- ◆ **install-dir** The installation process allows you to choose where to install SQL Anywhere, and the documentation refers to this location using the convention *install-dir*.

After installation is complete, the environment variable `SQLANY10` specifies the location of the installation directory containing the SQL Anywhere components (*install-dir*). `SQLANYSH10` specifies the location of the directory containing components shared by SQL Anywhere with other Sybase applications.

For more information on the default location of *install-dir*, by operating system, see “[File Locations and Installation Settings](#)” [*SQL Anywhere Server - Database Administration*].

- ◆ **samples-dir** The installation process allows you to choose where to install the samples that are included with SQL Anywhere, and the documentation refers to this location using the convention *samples-dir*.

After installation is complete, the environment variable `SQLANYXSAMP10` specifies the location of the directory containing the samples (*samples-dir*). From the Windows Start menu, choosing Programs ► SQL Anywhere 10 ► Sample Applications and Projects opens a Windows Explorer window in this directory.

For more information on the default location of *samples-dir*, by operating system, see “[The samples directory](#)” [*SQL Anywhere Server - Database Administration*].

- ◆ **Environment variables** The documentation refers to setting environment variables. On Windows, environment variables are referred to using the syntax *%envvar%*. On Unix, Linux, and Mac OS X, environment variables are referred to using the syntax *\$envvar* or *\${envvar}*.

Unix, Linux, and Mac OS X environment variables are stored in shell and login startup files, such as *.cshrc* or *.tcshrc*.

## Graphic icons

The following icons are used in this documentation.

- ◆ A client application.

- ◆ A database server, such as SQL Anywhere.

- ◆ An UltraLite application.

- ◆ A database. In some high-level diagrams, the icon may be used to represent both the database and the database server that manages it.

- ◆ Replication or synchronization middleware. These assist in sharing data among databases. Examples are the MobiLink server and the SQL Remote Message Agent.

- ◆ A Sybase Replication Server

- ◆ A programming interface.

## Finding out more and providing feedback

### Finding out more

Additional information and resources, including a code exchange, are available at the iAnywhere Developer Network at <http://www.ianywhere.com/developer/>.

If you have questions or need help, you can post messages to the iAnywhere Solutions newsgroups listed below.

When you write to one of these newsgroups, always provide detailed information about your problem, including the build number of your version of SQL Anywhere. You can find this information by entering **dbeng10 -v** at a command prompt.

The newsgroups are located on the *forums.sybase.com* news server. The newsgroups include the following:

- ◆ [sybase.public.sqlanywhere.general](#)
- ◆ [sybase.public.sqlanywhere.linux](#)
- ◆ [sybase.public.sqlanywhere.mobilink](#)
- ◆ [sybase.public.sqlanywhere.product\\_futures\\_discussion](#)
- ◆ [sybase.public.sqlanywhere.replication](#)
- ◆ [sybase.public.sqlanywhere.ultralite](#)
- ◆ [ianywhere.public.sqlanywhere.qanywhere](#)

#### **Newsgroup disclaimer**

iAnywhere Solutions has no obligation to provide solutions, information, or ideas on its newsgroups, nor is iAnywhere Solutions obliged to provide anything other than a systems operator to monitor the service and ensure its operation and availability.

iAnywhere Solutions Technical Advisors as well as other staff assist on the newsgroup service when they have time available. They offer their help on a volunteer basis and may not be available on a regular basis to provide solutions and information. Their ability to help is based on their workload.

### Feedback

We would like to receive your opinions, suggestions, and feedback on this documentation.

You can email comments and suggestions to the SQL Anywhere documentation team at [iasdoc@ianywhere.com](mailto:iasdoc@ianywhere.com). Although we do not reply to emails sent to that address, we read all suggestions with interest.

In addition, you can provide feedback on the documentation and the software through the newsgroups listed above.

---

# **Part I. Creating QAnywhere Applications**

This part shows you how to set up QAnywhere and write client applications.

---

QAnywhere architecture .....	7
QAnywhere message delivery .....	12
QAnywhere plug-in .....	13
Quick start .....	14

### About this chapter

QAnywhere is a comprehensive application-to-application messaging system for mobile users. It provides the infrastructure for you to write applications that exchange messages with remote applications located on a variety of devices running on Windows or Windows CE operating systems.

## QAnywhere application-to-application messaging

Application-to-application messaging permits communication between custom programs running on mobile or wireless devices and a centrally located server application. QAnywhere messaging is a useful application-to-application communication mechanism in a variety of situations:

- ◆ It provides messaging between mobile devices and between mobile devices and the enterprise.
- ◆ It provides communication in occasionally-connected environments.

The store-and-forward nature of messaging means that messages can be constructed even when the destination application is not reachable over the network; the message is delivered when the network becomes available.

QAnywhere messages are exchanged via a central server, so that the sender and recipient of a message never have to be connected to the network at the same time.

- ◆ It provides network-independent communication.

QAnywhere messages can be transported over TCP/IP, HTTP, or HTTPS protocols. They can also be delivered from a Windows CE handheld device by ActiveSync. The message itself is independent of the network protocol, and can be received by an application that communicates over a different network.

QAnywhere handles the challenges of wireless networks, such as slow speed, spotty geographic coverage, and dropped network connections. It can protect proprietary or sensitive information by encrypting all messages sent over public networks. You can customize the delivery of messages using transmission rules so that, for example, messages are transmitted during off-peak hours.

QAnywhere compresses and, optionally, encrypts data sent between mobile applications and enterprise servers. Furthermore, it implements a store-and-forward messaging paradigm that guarantees message delivery.

QAnywhere is designed for messaging solutions on a variety of handheld devices. This system provides a QAnywhere C++, Java, .NET, and SQL API to provide solutions to developers with different skill sets.

QAnywhere permits seamless communication with other messaging systems that have a JMS interface. This allows integration with J2EE applications.

---

## What QAnywhere does

QAnywhere provides the following application-to-application features and components.

- ◆ **QAnywhere API** The object-oriented QAnywhere API provides the infrastructure to build messaging applications for Windows desktop and Windows CE devices. The QAnywhere API is available in Java, C++, .NET, and SQL.
- ◆ **Store-and-forward** QAnywhere applications store messages locally until a connection between the client and the server is available for data transmission.
- ◆ **Complements data synchronization** QAnywhere applications use relational databases as a temporary message store. The relational database ensures that the message store has security, transaction-based computing, and the other benefits of relational databases.

The use of SQL Anywhere relational databases as message stores makes it easy to use QAnywhere together with a data synchronization solution. Both use MobiLink synchronization as the underlying mechanism for exchanging information between client and server.

- ◆ **Integration with external messaging systems** In addition to exchanging messages among QAnywhere applications, you can integrate QAnywhere clients into external messaging systems that support a JMS interface.
- ◆ **Encryption** Messages can be sent encrypted using transport-layer security. In addition, messages stores can be encrypted using simple encryption or any FIPS-approved AES algorithm.
- ◆ **Compression** Message content can be stored compressed using the popular ZLIB compression library.
- ◆ **Authentication** You can authenticate QAnywhere clients using a built-in facility or through custom authentication scripts (including existing authentication services used in your organization).
- ◆ **Multiple networks** QAnywhere works over any wired or wireless network that supports TCP/IP or HTTP.
- ◆ **Failover** You can run multiple MobiLink servers so that there are alternate servers in case one fails.
- ◆ **Administration** A QAnywhere application can browse and manipulate messages on the client and server side.
- ◆ **Multiple queues** Support for multiple arbitrarily-named queues on client devices permits multiple client applications to coexist on a single device. Applications can send and receive on any number of queues. Messages can be sent between applications that are coexisting on the same device and between applications on different devices.
- ◆ **Server-initiated send and receive** QAnywhere can push messages to client devices, allowing client applications to implement message-driven logic.
- ◆ **Transmission rules** You can create rules that specify when message transmission should occur.
- ◆ **Resumable downloads** Large messages or groups of messages are sent to QAnywhere clients in piecemeal fashion to minimize the retransmission of data during network failures.

- ◆ **Guaranteed delivery** QAnywhere guarantees the delivery of messages.
- ◆ **Mobile web services** Mobile web services facilitate the transport of web service requests and responses over QAnywhere.

## QAnywhere architecture

This section explains the architecture of QAnywhere messaging applications. The discussion begins with a simple messaging scenario and then progresses to more advanced scenarios.

Client applications send and receive messages using the QAnywhere API. Messages are queued in the client message store. Message transmission is the exchange of messages between client message stores through a central QAnywhere server message store.

The following typical messaging scenarios are supported by QAnywhere:

- ◆ **Simple messaging** For exchanging messages among QAnywhere clients. Client applications control when to transmit messages between the client and server message stores.

☞ See [“Simple messaging scenario” on page 7](#).

- ◆ **Messaging with push notifications** For exchanging messages among QAnywhere clients. In this scenario, the MobiLink server can initiate message transmission between clients. This is done by exchanging messages between client and server message stores.

☞ See [“Scenario for messaging with push notifications” on page 9](#).

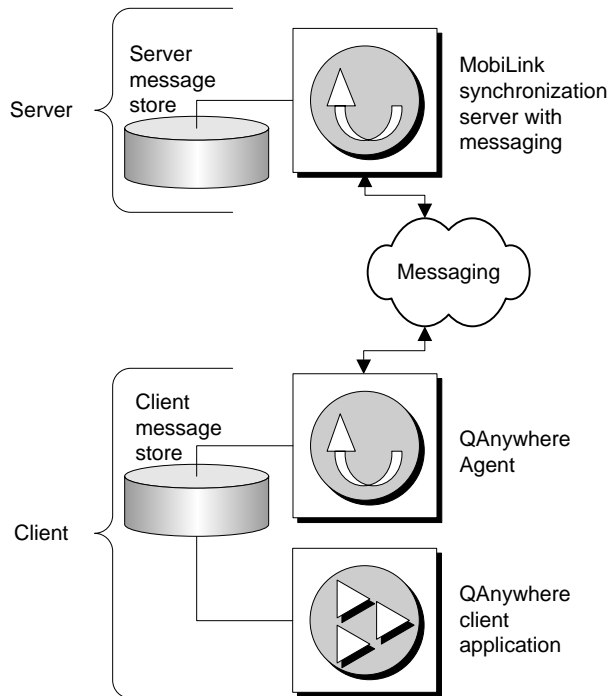

- ◆ **Messaging with external messaging systems** For exchanging messages among QAnywhere clients or an external system that supplies a JMS provider, such as BEA WebLogic or Sybase EAServer.

☞ See [“Scenario for messaging with external messaging systems” on page 11](#).

Push notifications and external messaging systems can be used together, providing the most general solution.

### Simple messaging scenario

A simple QAnywhere messaging setup is illustrated in the following diagram. For simplicity, only a single client is shown. However, a typical scenario has multiple clients with the server message store existing to transmit messages between them.

This setup includes the following components:

- ◆ **Server message store** At the server, the messages are stored in a relational database. The database must be set up as a MobiLink consolidated database, and may be any supported consolidated database (SQL Anywhere, Adaptive Server Enterprise, Microsoft SQL Server, DB2, or Oracle).
- ◆ **Client message store** The messages at each client are also stored in a relational database. The database used is SQL Anywhere.
- ◆ **MobiLink server with messaging** MobiLink synchronization provides the transport for transmitting and tracking messages between QAnywhere clients and the server. MobiLink provides security, authentication, encryption, and flexibility. It also allows messaging to be combined with data synchronization.

To manage QAnywhere message transmission, the MobiLink server must be started with messaging enabled. You do this by supplying the MobiLink server `-m` command line option.

☞ For more information, see [“Starting the MobiLink server for QAnywhere messaging” on page 31](#).

- ◆ **QAnywhere Agent** The QAnywhere Agent manages the transmission of messages on the client side. This process is independent of QAnywhere client applications.

☞ For more information, see [“Running the QAnywhere Agent” on page 35](#).

- ◆ **QAnywhere client application** An application written using the QAnywhere C++, Java, or .NET API makes method calls to send and receive messages. The basic object used by the client application is the `QAManager`.

☞ For information about writing applications using the QAnywhere API, see [“Writing QAnywhere Client Applications” on page 45](#).

Messages are sent and received by QAnywhere clients. Messages at the server will not be picked up until the client initiates a message transmission. QAnywhere clients use **policies** to determine when to carry out a message transmission. Policies include on-demand, automatic, scheduled, and custom. The on-demand policy permits the user to control message transmission. The automatic policy initiates a message transmission whenever a message to or from the client is ready for delivery.

☞ For more information, see [“Determining when message transmission should occur on the client” on page 36](#).

## Scenario for messaging with push notifications

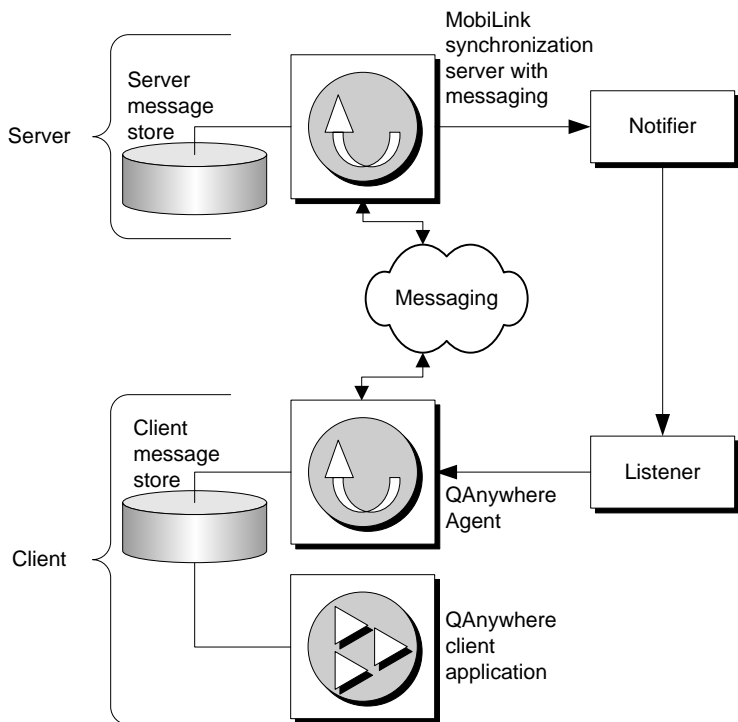

A push notification is a special message delivered from the server to a QAnywhere client. The push notification occurs when a message arrives at the server message store. The messaging server automatically notifies the recipient client Listener of the push request. The client initiates message transmission to receive messages waiting at the server or takes a custom action.

☞ For more information about the client's response to a push notification, see [“Determining when message transmission should occur on the client” on page 36](#).

Push notifications introduce two extra components to the QAnywhere architecture. At the server, a QAnywhere Notifier sends push notifications. At the client, a QAnywhere Listener receives these push notifications and passes them on to the QAnywhere Agent.

If you do not use push notifications, messages are still transmitted from the server message store to the client message store, but the transmission must be initiated at the client, such as by using a scheduled transmission policy.

The architecture for messaging with push notifications is an extension of that described in [“Simple messaging scenario” on page 7](#). The following diagram shows this architecture:

The following components are added to the “[Simple messaging scenario](#)” on page 7 enable push notification:

- ◆ **QAnywhere Notifier** The Notifier is the component of the MobiLink server that is used to deliver push notifications.  
 The QAnywhere Notifier is a specially configured instance of the Notifier that sends push notifications when a message is ready for delivery.
- ◆ **QAnywhere Listener** The QAnywhere Listener is a separate process that runs at the client. It receives push notifications and passes them on to the QAnywhere Agent. QAnywhere Agent policies determine if push notifications automatically cause message transmission.

☞ For more information, see “[Determining when message transmission should occur on the client](#)” on page 36.

**See also**

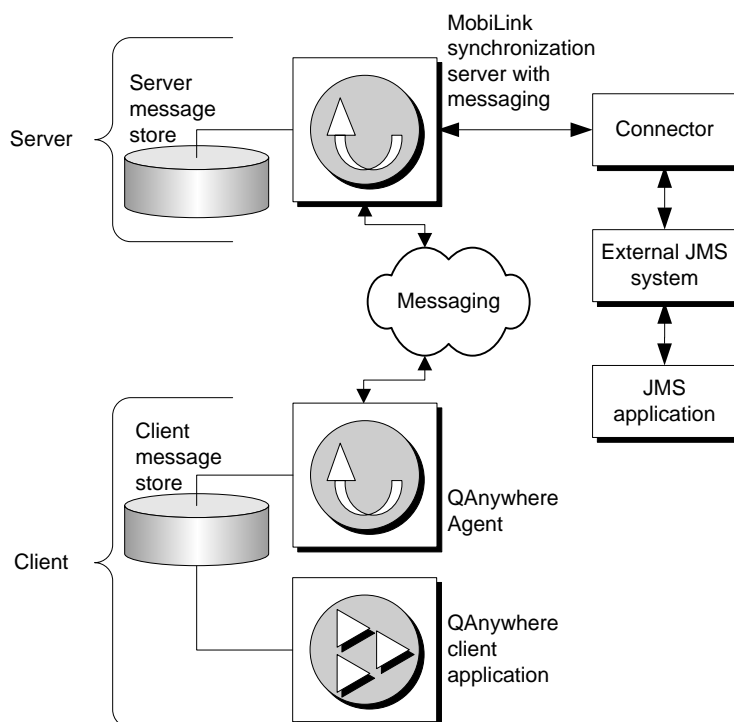

- ◆ “[Using push notifications](#)” on page 41
- ◆ “[Receiving messages asynchronously](#)” on page 76
- ◆ “[Introducing Server-Initiated Synchronization](#)” [*MobiLink - Server-Initiated Synchronization*]

## Scenario for messaging with external messaging systems

In addition to exchanging messages among QAnywhere applications, you can exchange messages with systems that have a JMS interface using a specially configured client known as a connector. JMS is the Java Message Service API for adding messaging capabilities to Java applications.

The external messaging system is set up to act like a special client. It has its own address and configuration.

The architecture for messaging with external messaging systems is an extension of the architecture described in [“Simple messaging scenario” on page 7](#). The following diagram shows this architecture:

The component that is added to [“Simple messaging scenario” on page 7](#) in order to enable messaging with an external messaging system is as follows:

- ◆ **QAnywhere JMS Connector** The JMS Connector provides an interface between QAnywhere and the external messaging system.

The JMS Connector is a special QAnywhere client that moves messages between QAnywhere and the external JMS system.

### See also

- ◆ [“JMS Connectors” on page 127](#)
- ◆ [“Tutorial: Using JMS connectors” on page 141](#)

## QAnywhere message delivery

Messages are sent from a client message store to a server message store, and then on to another client message store. QAnywhere does this via queues: a message is put on a queue in the client message store; when it is received by the server message store, it is put on a queue for delivery to one or more client message stores; and when it is received by a client message store, it is put on a queue for pickup.

Once a message is sent, it will be delivered unless one of the following occurs:

- ◆ The message expires (only if an expiration is specified).
- ◆ The message is cancelled via Sybase Central.
- ◆ The device from which the message is sent is lost unrecoverably before it can synchronize with the server message store (or for some other reason, synchronization is impossible).

A message will not be delivered more than once. If an application successfully acknowledges or commits the receipt of a message, then the same message will not be delivered again. There is a possible exception with JMS servers: in the event of the MobiLink server or JMS server crashing, there is a possibility that a message will be delivered twice.

## QAnywhere plug-in

The Sybase Central QAnywhere plug-in helps you create and administer your QAnywhere application. With the plug-in, you can:

- ◆ Create client and server message stores.
- ◆ Create and maintain configuration files for the QAnywhere Agent.
- ◆ Browse QAnywhere Agent log files.
- ◆ Create or modify destination aliases.
- ◆ Create JMS connectors and web service connectors.
- ◆ Create and maintain transmission rules files.
- ◆ Browse message stores remotely.
- ◆ Track messages.

### ◆ To start the QAnywhere plug-in

1. Start Sybase Central:  
Choose Start ► Programs ► SQL Anywhere 10 ► Sybase Central.
2. From Connections, choose Connect with QAnywhere 10.
3. Specify an ODBC data source name or file, and a user ID and password if required.
4. Click OK.

## Quick start

The following steps provide an overview of the tasks required to set up and run QAnywhere messaging.

### ◆ To set up and run QAnywhere messaging

1. Set up a server message store or use an existing MobiLink consolidated database.
    - ☞ See [“Setting up the server message store” on page 30](#).
  2. Start the MobiLink server with the -m option and a connection to the server message store.
    - ☞ See [“Starting the MobiLink server for QAnywhere messaging” on page 31](#).
  3. Set up client message stores. These are SQL Anywhere databases that are used to temporarily store messages.
    - ☞ See [“Setting up the client message store” on page 33](#).
  4. For each client, write a messaging application.
    - ☞ See [“Writing QAnywhere Client Applications” on page 45](#).
  5. If you want to integrate with an external JMS messaging system, set up JMS messaging for QAnywhere.
    - ☞ See [“JMS Connectors” on page 127](#).
  6. For each client, start the QAnywhere Agent with a connection to the local client message store.
    - ☞ See [“Running the QAnywhere Agent” on page 35](#).
- ☞ For information about setting up mobile web services, see [“Mobile Web Services” on page 181](#).

Lesson 4: Explore the TestMessage client source code .....	23
Tutorial cleanup .....	27

### About this chapter

This tutorial explores the capabilities of QAnywhere through a sample client application named TestMessage. QAnywhere applications can run on many devices, such as PDAs, laptops, and tablets, extending application-to-application messaging to these devices. However, for demonstration purposes, this tutorial runs the client on a Windows computer.

## About the tutorial

TestMessage is a sample QAnywhere client application. This application demonstrates how you can use QAnywhere to create your own messaging client applications. TestMessage provides a single client-to-client interface to send, receive, and display messages. Being human-readable, text messages provide a useful demonstration of QAnywhere messaging, but QAnywhere provides much more than text messaging. It is a general purpose application-to-application messaging system that provides message-based communication among many clients.

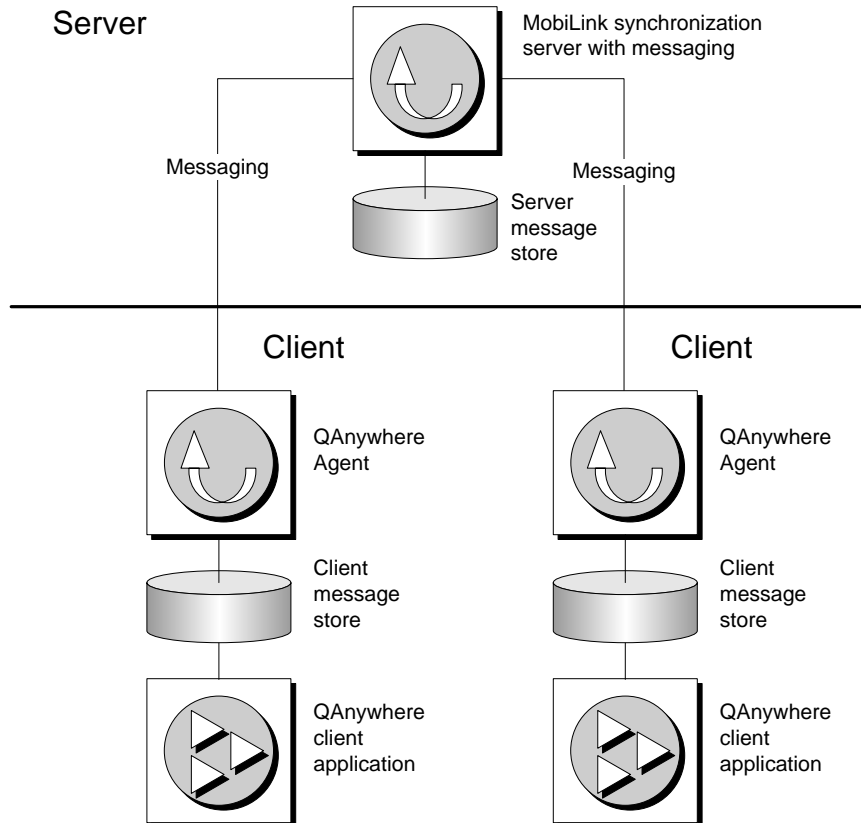

The tutorial is written for a Windows desktop system. While these platforms are convenient for demonstration purposes, you can also use the QAnywhere API to write applications that run on Windows CE devices. Source code is provided for Windows CE for C++, Visual Basic .NET, C#, and Java. There is also a C# version written on the .NET Compact Framework.

## Lesson 1: Start MobiLink with messaging

### Background

QAnywhere uses MobiLink synchronization to send and receive messages. All messages from one client to another are delivered through a central MobiLink server. The architecture of a typical system, with only two QAnywhere clients, is shown in the following diagram.

The server message store is a database configured for use as a MobiLink consolidated database. The TestMessage sample uses a SQL Anywhere consolidated database as its server message store.

The only tables needed in the server message store are the MobiLink system tables that are included in any supported database that is set up as a MobiLink consolidated database.

The system tables are maintained by MobiLink. A relational database provides a secure, high performance message store. It enables you to easily integrate messaging into an existing data management and synchronization system.

QAnywhere messaging is usually carried out over separate computers, but in this tutorial all components are running on a single computer. It is important to keep track of which activities are client activities and which are server activities.

In this lesson, you carry out actions at the server.

### Activity

The MobiLink server can be started with messaging by supplying the `-m` option, as well as specifying a connection string to the server message store. The TestMessage sample uses a QAnywhere sample database for the server message store. For the TestMessage sample, you can start the MobiLink server for messaging using the command line options, using a sample shortcut in your SQL Anywhere installation, or with the QAnywhere plug-in to Sybase Central.

#### ◆ Start the messaging server

1. From the Windows Start menu, choose Programs ► SQL Anywhere 10 ► MobiLink ► MobiLink with Messaging Sample.

Alternatively, at a command prompt, navigate to `samples-dir\QAnywhere\server` and type the following command:

```
mlsrv10 -m -c "dsn=QAnywhere 10 Demo" -vcrs -zu+
```

This command line uses the following mlsrv10 options:

Option	Description
-m	The <code>-m</code> option enables messaging.  See “-m option” [ <i>MobiLink - Server Administration</i> ].
-c	The <code>-c</code> option specifies the connection string to the server message store, in this case using the QAnywhere 10.0 Demo ODBC data source.  See “-c option” [ <i>MobiLink - Server Administration</i> ].
-vcrs	The <code>-vcrs</code> option provides verbose logging of server activities, which is useful during development.  See “-v option” [ <i>MobiLink - Server Administration</i> ].
-zu+	The <code>-zu+</code> option automatically adds user names to the system; this is convenient for tutorial or development purposes but is not normally used in a production environment.  See “-zu option” [ <i>MobiLink - Server Administration</i> ].

2. Move the MobiLink server window to the center of your screen, which represents the server in this tutorial.

Once the MobiLink server is started, you can move on to the next lesson.

### Further reading

- ◆ “Starting the MobiLink server for QAnywhere messaging” on page 31
- ◆ “-m option” [*MobiLink - Server Administration*]
- ◆ “Quick start” on page 14

- ◆ [“Simple messaging scenario” on page 7](#)

## Lesson 2: Run the TestMessage application

### Background

TestMessage is a simple application that uses QAnywhere to send and receive text messages. Text messaging is used in this tutorial because it provides a simple and accessible demonstration of messaging. QAnywhere is, however, not just a text messaging system; it provides general purpose application-to-application messaging.

In this lesson, you are carrying out activities at a client. Typically, clients run on separate computers from the server.

In this lesson, you start the client message store that is part of the TestMessage sample. In Lesson 3, you will use this message store to send a message to another client message store.

### Activity

#### ◆ To start the QAnywhere Agent with the TestMessage client message store

1. From the Start menu, choose Programs ► SQL Anywhere 10 ► QAnywhere ► Agent for Client1 Sample.

This starts an instance of the QAnywhere Agent. This Agent connects to the first TestMessage sample client message store and manages message transmission to and from this message store.

2. Move the first QAnywhere Agent window to the right side of your screen, which represents the first client in this tutorial.

3. From the Start menu, choose Programs ► SQL Anywhere 10 ► QAnywhere ► Agent for Client2 Sample.

This starts another instance of the QAnywhere Agent. This Agent connects to the second TestMessage sample client message store and manages message transmission to and from this message store.

4. Move the second QAnywhere Agent window to the left side of your screen, which represents the second client in this tutorial.

5. Each of the QAnywhere Agent windows displays a client message store ID, called client1 and client2.

#### ◆ To start TestMessage

1. From the Windows Start menu, choose Programs ► SQL Anywhere 10 ► QAnywhere ► TestMessage for Client1 Sample.

The TestMessage window is displayed. The application is connected to the first TestMessage client message store that you started in the above procedure.

2. Move the TestMessage window to the right side of your screen, together with the first QAnywhere Agent. Both these components belong on the first client.

3. Check the message queue.

From the TestMessage - client 1 Tools menu, choose Options. You will see that the queue name **testmessage** is specified. This is the queue that the TestMessage application is listening on for incoming messages. Do not change this name.

4. From the Windows Start menu, choose Programs ► SQL Anywhere 10 ► QAnywhere ► TestMessage for Client2 Sample.

The TestMessage window is displayed. The application is connected to the second TestMessage client message store that you started in the above procedure.

5. Move the TestMessage window to the left side of your screen, together with the second QAnywhere Agent. Both these components belong on the second client.
6. Check the message queue.

From the TestMessage - client 2 Tools menu, choose Options. You will see that the queue name **testmessage** is specified. This is the queue that the TestMessage application is listening on for incoming messages. Do not change this name.

## Discussion

You can configure the way that the QAnywhere Agent monitors messages by setting a message transmission policy. This sample starts the QAnywhere Agent using the automatic policy.

- ◆ **scheduled** This policy setting instructs the QAnywhere Agent to transmit messages periodically. If you don't specify an interval, the default is 15 minutes.
- ◆ **automatic** This default policy setting causes the QAnywhere Agent to transmit messages whenever a message to or from the client message store is ready for delivery.
- ◆ **ondemand** This policy setting causes the QAnywhere Agent to transmit messages only when instructed to by an application.
- ◆ **custom** In this mode, you provide a set of rules to specify more complicated transmission behavior.

QAnywhere messages are delivered to a QAnywhere address, which consists of a client message store ID and a queue name. The default ID is the computer name on which the QAnywhere Agent is running. Each message store requires its own QAnywhere Agent. Each application can listen to multiple queues, but each queue should be specific to a single application.

## Further reading

- ◆ [“Running the QAnywhere Agent” on page 35](#)
- ◆ [“Determining when message transmission should occur on the client” on page 36](#)
- ◆ [“qaagent syntax” on page 145](#)
- ◆ [“QAnywhere Transmission and Delete Rules” on page 225](#)
- ◆ [“Writing QAnywhere Client Applications” on page 45](#)
- ◆ QAnywhere samples, which are installed to *samples-dir*\QAnywhere. (For more information about *samples-dir*, see [“The samples directory” \[SQL Anywhere Server - Database Administration\]](#).)

## Lesson 3: Send a message

### Background

The TestMessage sample includes two client message stores, which you started in Lesson 1. In this lesson you will send a message from the TestMessage client1 application to the TestMessage client2 application.

### Activity

#### ◆ To send a message from TestMessage

1. From the TestMessage - client1 Message menu, choose New. The New Message window appears.
2. In the Destination ID field, enter client2. (Leave testmessage in the Destination Queue field.)
3. Fill out the Subject and Message fields with sample text, and click Send.

When testing messaging, it is often useful to use the current time as a subject line to make it easy to track individual messages.

An Alert appears.

4. Read the message.

Switch to the TestMessage client2 window. Select the message to display its contents in the bottom pane of the window.

### Discussion

Like other QAnywhere applications, TestMessage uses the QAnywhere API to manage messages. The QAnywhere API is supplied as a C++ API, a Java API, a Microsoft .NET API, and a SQL API.

### Further reading

- ◆ [“QAnywhere message addresses” on page 50](#)
- ◆ [“Sending QAnywhere messages” on page 66](#)
- ◆ [“Message delete rules” on page 239](#)

## Lesson 4: Explore the TestMessage client source code

### Background

This section of the tutorial takes you on a brief tour of the source code behind the TestMessage client application.

A good deal of the code implements the Windows interface, through which you can send, receive, and view the messages. This portion of the tutorial, however, focuses on the portions of the code given to QAnywhere.

You can find the TestMessage source code in the *samples-dir\QAnywhere*.

Several versions of the TestMessage source code are provided. The following versions are provided for Windows 2000 and Windows XP:

- ◆ A C++ version built using the Microsoft Foundation Classes is provided as *Samples\QAnywhere\Desktop\MFC\TestMessage\TestMessage.sln*.
- ◆ A Visual Basic .NET version built on the .NET Framework is provided as *Samples\QAnywhere\Desktop\NET\VB\TestMessage\TestMessage.sln*.
- ◆ A C# version built on the .NET Framework is provided as *Samples\QAnywhere\Desktop\NET\CS\TestMessage\TestMessage.sln*.
- ◆ A Java version is provided as *Samples\QAnywhere\Java\TestMessage\TestMessage.java*.

The following version is provided for Pocket PC:

- ◆ A C# version built on the .NET Compact Framework is provided as *Samples\QAnywhere\PocketPC\NET\CS\TestMessage\TestMessage.sln*.

### Required software

Visual Studio .NET 2003 or later is required to open the solution files and build the .NET Framework projects and the .NET Compact Framework project.

### Exploring the C# source

This section takes you through the C# source code. The two versions are structured in a very similar manner.

Rather than look at each line in the application, this lesson highlights particular lines that are useful for understanding QAnywhere applications. It uses the C# version to illustrate these lines.

1. Open the version of the TestMessage project that you are interested in.

Double-click the solution file to open the project in Visual Studio .NET. For example, *Samples\QAnywhere\Desktop\NET\CS\TestMessage\TestMessage.sln* is a solution file. There are several solution files for different environments.

2. Ensure the Solution Explorer is open.

You can open the Solution Explorer from the View menu.

3. Inspect the Source Files folder.

There are two files of particular importance. The *MessageList* file (*MessageList.cs*) receives messages and lets you view them. The *NewMessage* file (*NewMessage.cs*) allows you to construct and send messages.

4. From the Solution Explorer, open the *MessageList* file.
5. Inspect the included namespaces.

Every QAnywhere application requires the *iAnywhere.QAnywhere.Client* namespace. The assembly that defines this namespace is supplied as the DLL *iAnywhere.QAnywhere.Client.dll*. The locations for this file are (relative to your SQL Anywhere installation directory):

- ◆ .NET Framework 1.1: `\Assembly\v1`
- ◆ .NET Framework 2.0: `\Assembly\v2`
- ◆ .NET Compact Framework 1.0: `ce\Assembly\v1`
- ◆ .NET Compact Framework 2.0: `ce\Assembly\v2`

For your own projects, you must include a reference to this DLL when compiling. The namespace is included using the following line at the top of each file:

```
using iAnywhere.QAnywhere.Client;
```

6. Inspect the `startReceiver` method.

This method performs initialization tasks that are common to QAnywhere applications:

- ◆ Create a *QAManager* object.

```
_qaManager =  
    QAManagerFactory.Instance.CreateQAManager( null );
```

QAnywhere provides a *QAManagerFactory* object to create *QAManager* objects. The *QAManager* object handles QAnywhere messaging operations: in particular, receiving messages (getting messages from a queue) and sending messages (putting messages on a queue).

QAnywhere provides two types of manager: *QAManager* and *QATransactionalManager*. When using *QATransactionalManager*, all send and receive operations occur within a transaction, so that either all messages are sent (or received) or none are.

- ◆ Write a method to handle messages.

The `onMessage()` method is called by QAnywhere to handle regular non-system messages. The message it receives is encoded as a *QAMessage* object. The *QAMessage* class and its children, *QATextMessage* and *QABinaryMessage*, provide properties and methods that hold all the information QAnywhere applications need about a message.

```
private void onMessage( QAMessage msg ) {  
    Invoke( new onMessageDelegate( onMessageReceived ),  
        new Object [] { msg } );  
}
```

This code uses the `Invoke` method of the `Form` to cause the event to be processed on the thread that runs the underlying window so that the user interface can be updated to display the message. This

is also the thread that created the QAManager. With some exceptions, the QAManager can only be accessed from the thread that created it.

- ◆ Declare a MessageListener.

```
_receiveListener = new
    QAManager.MessageListener( onMessage );
```

The OnMessage() method is called whenever a message is received by the QAnywhere Agent and placed in the queue that the application listens to.

#### Message listeners and notification listeners

Message listeners are different from the Listener component described in “[Scenario for messaging with push notifications](#)” on page 9. The Listener component receives notifications, while message listener objects retrieve messages from the queue.

When you set a message listener for the queue, the QAnywhere Manager passes messages that arrive on that queue to that listener. Only one listener can be set for a given queue. Setting with a null listener clears out any listener for that queue.

The MessageListener implementation receives messages asynchronously. You can also receive messages synchronously; that is, the application explicitly goes and looks for messages on the queue, perhaps in response to a user action such as clicking a Refresh button, rather than being notified when messages appear.

Other initialization tasks include:

- ◆ Open and start the QAManager object.

```
_qaManager.Open(
    AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT );
_qaManager.Start();
```

The AcknowledgementMode enumeration constants determine how the receipt of messages is acknowledged to the sender. The EXPLICIT\_ACKNOWLEDGEMENT constant indicates that messages are not acknowledged until a call to one of the QAManager acknowledge methods is made.

- ◆ Load any messages that are waiting in the queue.

```
loadMessages();
```

- ◆ Assign a listener to a queue for future messages.

The listener was declared in the MessageList\_Load() method.

```
_qaManager.SetMessageListener(
    _options.ReceiveQueueName,
    _receiveListener );
```

The Options ReceiveQueueName property contains the string **testmessage**, which is the TestMessage queue as set in the TestMessage Options dialog.

7. Inspect the `addMessage()` method in the same file.

This method is called whenever the application receives a message. It gets properties of the message such as its reply-to address, preferred name, and the time it was sent (Timestamp), and displays the information in the TestMessage user interface. The following lines cast the incoming message into a `QATextMessage` object and get the reply-to address of the message:

```
text_msg = ( QATextMessage )msg;
from = text_msg.ReplyToAddress;
```

This completes a brief look at some of the major tasks carried out in the *MessageList* file.

8. From the Solution Explorer, open the *NewMessage* file.
9. Inspect the `sendMessage()` method.

This method takes the information entered in the New Message dialog and constructs a `QATextMessage` object. The `QAManager` then puts the message in the queue to be sent.

Here are the lines that create a `QATextMessage` object and set its `ReplyToAddress` property:

```
qa_manager = MessageList.GetQAManager();
msg = qa_manager.CreateTextMessage();
msg.ReplyToAddress = MessageList.getOptions().ReceiveQueueName;
```

Here are the lines that put the message in the queue to be sent. The variable `to` is the destination address, supplied as an argument to the function.

```
qa_manager.PutMessage( dest, msg );
```

## Tutorial cleanup

Shut down all instances of TestMessage, the QAnywhere Agent, and the MobiLink server.

---

---

CHAPTER 3

# Setting Up QAnywhere Messaging

## Contents

Setting up server-side components ..... 30

Setting up client-side components ..... 33

Using push notifications ..... 41

Setting up a failover mechanism ..... 42

### About this chapter

This chapter describes how to set up and run QAnywhere messaging.

QAnywhere uses MobiLink synchronization to transport messages. This chapter describes how to set up and run the MobiLink server with messaging.

## Setting up server-side components

### ◆ Overview of setting up QAnywhere server-side components

1. Set up a server message store and start it. This can be any MobiLink consolidated database.  
☞ See [“Setting up the server message store” on page 30](#).
2. Start mlsrv10 with the -m option and a connection to the server message store.  
☞ See [“Starting the MobiLink server for QAnywhere messaging” on page 31](#).
3. Add client user names to the server message store.  
☞ See [“Registering client user names” on page 31](#).

### Setting up the server message store

The server message store is a relational database on the server that temporarily stores messages until they are transmitted to a client message store, web service or JMS system. Messages are exchanged between clients via the server message store.

A server message store is a MobiLink consolidated database, and so can be any RDBMS that MobiLink supports (SQL Anywhere, Adaptive Server Enterprise, Microsoft SQL Server, Oracle, or DB2). You can create a new database for this purpose, or use an existing database.

To set up a database to use as a MobiLink consolidated database (and hence a server message store), you must run a setup script.

☞ See [“Setting up a consolidated database” \[MobiLink - Server Administration\]](#).

☞ For information about creating SQL Anywhere databases, see [“The Initialization utility” \[SQL Anywhere Server - Database Administration\]](#).

If you are using a SQL Anywhere database that was created before version 9.0.2, it must be upgraded.

☞ For information on upgrading your database, see [“Upgrading to SQL Anywhere 10” \[SQL Anywhere 10 - Changes and Upgrading\]](#).

### Example

To create a SQL Anywhere database called *qanytest.db*, type the following at a command prompt:

```
dbinit -n -s qanytest.db
```

Run the MobiLink setup script on the database:

```
%SQLANY10%\MobiLink\setup\syncsa.sql
```

This database is ready to use as a server message store.

## Starting the MobiLink server for QAnywhere messaging

QAnywhere uses MobiLink synchronization to transport messages. To use QAnywhere messaging, you must start the MobiLink server (mlsrv10) with the following options:

- ◆ **-c *connection-string*** Specifies the connection string to connect to the server message store.

☞ See “-c option” [*MobiLink - Server Administration*].

- ◆ **-m** Enables QAnywhere messaging.

☞ See “-m option” [*MobiLink - Server Administration*].

☞ You can also use other MobiLink server options to customize your operations. For more information, see “mlsrv10 syntax” [*MobiLink - Server Administration*].

### Notes

- ◆ If you are integrating with a JMS messaging system, there are other options you must specify when you start the MobiLink server.

See “Starting the MobiLink server for JMS integration” on page 131.

### Example

To start QAnywhere messaging when you are using a server message store called *qanyserv.db*, navigate to *samples-dir\QAnywhere\server* and type the following at a command prompt (all on one line):

```
mlsrv10 -m
        -c "dsn=QAnywhere 10 Demo"
```

For information about *samples-dir*, see “The samples directory” [*SQL Anywhere Server - Database Administration*].

## Registering client user names

Each client message store has a unique ID that identifies it. In addition, the client message store has a MobiLink user name that you can optionally use to authenticate your client message store with the MobiLink server. You can specify a MobiLink user name with the *qaagent -mu* option, or if you do not, one is created with the same name as your client message store ID.

You must register the MobiLink user name with the server message store. There are several methods for doing this:

- ◆ Use the *mluser* utility.

For more information, see “MobiLink user authentication utility [*mluser*]” [*MobiLink - Server Administration*].

- ◆ Use MobiLink Admin mode in Sybase Central.
- ◆ Specify the `-zu+` option with `mlsrv10`. In this case, any existing MobiLink users that have not been added to the consolidated database are added when they first synchronize. This is useful during development, but is not recommended for production environments.

For more information, see “[-zu option](#)” [*MobiLink - Server Administration*].

☞ For more information about MobiLink user names, see “[About MobiLink users](#)” [*MobiLink - Client Administration*].

☞ For more information about client message store IDs, see “[-id option](#)” on page 152.

### Setting properties for clients on the server

As a convenience, you can use the QAnywhere plug-in to set properties for clients on the server. When you do this, you need to add the client to the server. The first time you synchronize to the client, the properties will be downloaded.

#### ◆ To add a client user name using Sybase Central

1. Start Sybase Central:
  - ◆ Choose Start ► Programs ► SQL Anywhere 10 ► Sybase Central.
  - ◆ From Connections, choose Connect with QAnywhere 10.
  - ◆ Specify an ODBC data source name or file, and a user ID and password if required. Click OK.
2. Choose File ► New ► Client.
3. Type the name of the client.
4. Click OK.

#### See also

- ◆ “[Registering client user names](#)” on page 31

## Setting up client-side components

### ◆ Overview of setting up client-side components

1. Create a SQL Anywhere database and initialize it as a client message store.
  - ☞ See [“Setting up the client message store” on page 33.](#)
2. Write client applications.
  - ☞ See [“Writing QAnywhere Client Applications” on page 45.](#)
3. Start the QAnywhere Agent.
  - ☞ See [“Running the QAnywhere Agent” on page 35.](#)

### Setting up the client message store

The client message store is a SQL Anywhere database on the remote device. The application connects to this message store using the QAnywhere API.

Using a relational database as a message store provides a secure and high-performance store.

☞ See also: [“Creating a secure client message store” on page 176.](#)

### ◆ To create a client message store

1. Create a SQL Anywhere database.

Note: QAnywhere does not use or manage a transaction log. You can create a database with a transaction log if you want to use one for backups or other uses, but it may grow very large. In most cases, it is recommended that your client message store not have a transaction log.

☞ See [“Creating a database” \[SQL Anywhere Server - SQL Usage\]](#).

2. Initialize each client message store by running the QAnywhere Agent (qaagent) with the following options:

◆ **-c option** to specify a connection string to the database you just created.

☞ See [“-c option” on page 148.](#)

◆ **-si option** to initialize the database. The -si option creates a default database user and password. The QAnywhere agent shuts down after initializing the database.

☞ See [“-si option” on page 169.](#)

◆ **-id option** optionally, if you want to pre-assign a client message store ID.

☞ See [“Creating client message store IDs” on page 34](#) and [“-id option” on page 152](#).

- ◆ **-mu option** optionally, if you want to create a user name to use for authentication with the MobiLink server. If you do not use -mu at this point, you can specify it any time you start the QAnywhere Agent and the name will be created if it does not already exist.

3. If you used the -mu option to create a user name, you need to add the name to the server message store. This can be done automatically using the mlsrv10 -zu+ option, or can be done in other ways.

☞ See [“Registering client user names” on page 31](#).

4. Change the default passwords and take other steps to ensure that the client message store is secure.

☞ See [“Creating a secure client message store” on page 176](#).

You can also upgrade a client message store that was created in a previous version of QAnywhere.

☞ See [“-su option” on page 170](#) and [“-sur option” on page 171](#).

### Creating client message store IDs

Client message store IDs can be set in various ways:

- ◆ You can specify the ID with the qaagent -id option when you use the qaagent -si option to initialize the client message store.
- ◆ You can specify the ID with the -id option the first time you run qaagent after you initialize the client message store.
- ◆ If you do not specify an ID in either of the previous ways, then the first time you run qaagent after you run qaagent with -si, the device name is assigned as the client message store ID. The ID appears in the QAnywhere Agent window.

☞ For more information, see [“QAnywhere Agent” on page 143](#).

### Example of creating a client message store

The following command creates a SQL Anywhere database called qanyclient.db. (The dbinit -i and -s options are not required, but are good practice on small devices.)

```
dbinit -i -n -s qanyclient.db
```

The following command connects to *qanyclient.db* and initializes it as a QAnywhere client database:

```
qaagent -si -c "DBF=qanyclient.db"
```

☞ For more information about dbinit, see [“Initialization utility \(dbinit\)” \[SQL Anywhere Server - Database Administration\]](#).

## Running the QAnywhere Agent

The QAnywhere Agent (qaagent) is a separate process running on the client device. It monitors the client message store and determines when message transmission should occur.

The QAnywhere Agent transmits messages between the server message store and the client message store. You can run multiple instances of the QAnywhere Agent on the same device, but each instance must be connected to its own message store. Each message store must have a unique message store ID.

You can run the Agent on the command line using command line options. At a minimum, you need to start the Agent with the following options:

◆ **Connection parameters** to connect to the client message store.

In the Agent command file properties dialog, this is the information on the Message Store tab.

In the qaagent command line, this is specified with the -c option.

☞ See “-c option” on page 148.

◆ **Client message store ID** to identify the client message store. The first time you run qaagent after you have initialized a client message store, you can optionally use this option to name the message store; if you do not, the device name is used by default. After that, you must use the -id option every time you start qaagent to specify a unique client message store ID.

In the Agent Command file properties dialog, this is specified on the General tab.

In the qaagent command line, this is specified with the -id option.

☞ See “-id option” on page 152.

◆ **Network protocol and protocol options** to connect to the MobiLink server. This is required unless the MobiLink server is running on the same device as the QAnywhere agent and default communication parameters are used.

In the Agent command file properties dialog, this is the server information on the Server tab.

In the qaagent command line, this is the -x option.

☞ See “-x option” on page 173.

☞ For a complete list of all QAnywhere Agent options, see “qaagent syntax” on page 145.

### Starting qaagent on Windows CE

On Windows CE, you might want to start the QAnywhere Agent in quiet mode by specifying the -qi option.

☞ See “-qi option” on page 168.

### Running multiple instances of QAnywhere Agent

You can run multiple instances of qaagent on a device. However, when you start a second instance:

- ◆ The second instance of QAnywhere Agent must be started with a different database file.
- ◆ You must specify a unique message store ID using the `-id` option.

See [“-id option” on page 152](#).

### Stopping QAnywhere Agent

To stop the QAnywhere Agent, click Shutdown on the console.

When you start the QAnywhere Agent in quiet mode, you can only stop it by running **qastop**.

☞ See [“-qi option” on page 168](#).

### Processes started by QAnywhere Agent

The QAnywhere Agent starts other processes to handle various messaging tasks. Each of these processes is managed by the QAnywhere Agent, and does not need to be managed separately. When you start the QAnywhere Agent, it spawns the following processes:

- ◆ **dbmlsync** The `dbmlsync` executable is the MobiLink synchronization client. MobiLink synchronization is used to send and receive messages, so the `dbmlsync` executable is required.
- ◆ **dblsn** The `dblsn` executable is the Listener utility. It receives push notifications. If you are not using push notifications, you do not need to supply the `dblsn` executable when you deploy your application, and you must run `qaagent` with `-push none`.

☞ See [“-push option” on page 165](#).

- ◆ **database server** The client message store is a SQL Anywhere database. QAnywhere Agent requires the SQL Anywhere database server to run the database. For Windows CE, the database server is `dbsrv10.exe`. For Windows, the database server is the personal database server `dbeng10.exe`.

The QAnywhere Agent can spawn a database server or connect to a running server, depending on the communication parameters that you specify in the `qaagent -c` option.

☞ See [“-c option” on page 148](#).

### Deploying QAnywhere Agent

☞ For deployment information, see [“Deploying QAnywhere applications” on page 89](#).

### Determining when message transmission should occur on the client

On the client side, you determine when message transmission should occur by specifying **policies**. A policy tells the QAnywhere Agent when a message should be moved from the client message store to the server message store. If you do not specify a policy, transmission occurs automatically when a message is queued for delivery to the server by default. There are three pre-defined policies: scheduled, automatic, and ondemand, as well as a custom policy.

You can specify policies in two ways:

- ◆ Using the QAnywhere plug-in in Sybase Central, choose the task Create an Agent Command File. Policies are specified on the General tab of the command file Properties dialog.

To specify custom properties, you must also choose the task Create an Agent Rule File. This task creates a file with a *.qar* extension; this extension is a Sybase Central convention.

- ◆ Run `qaagent` on the command line using the `-policy` option. For custom policies, create a rules file and specify it.

### Scheduled policy

The scheduled policy instructs the Agent to perform a transmission at a specified time interval.

To invoke a schedule, choose **scheduled** in the command file Properties dialog or specify the keyword when you start the QAnywhere Agent:

```
qaagent -policy scheduled [ interval ] ...
```

where *interval* is in seconds.

The default is 900 seconds (15 minutes).

When a schedule is specified, every *n* seconds the Agent performs message transmission if any of the following conditions are met:

- ◆ New messages were placed in the client message store since the previous time interval elapsed.
- ◆ A message status change occurred since the previous time interval elapsed. This typically occurs when a message is acknowledged by the application.

For more information about acknowledgement, see [“AcknowledgementMode enumeration” on page 244](#) for .NET clients, [“AcknowledgementMode class” on page 392](#) for C++ clients and [“Interface AcknowledgementMode” on page 504](#) for Java clients.

- ◆ A push notification was received since the previous time interval elapsed.
- ◆ A network status change notification was received since the previous time interval elapsed.
- ◆ Push notifications are disabled.

You can call the `trigger send receive` method to override the time interval. It forces message transmission to occur before the time interval elapses.

For more information about `trigger send receive`, see:

- ◆ .NET: [“TriggerSendReceive method” on page 309](#)
- ◆ C++: [“triggerSendReceive function” on page 461](#)
- ◆ Java: [“setStringStoreProperty method” on page 564](#)
- ◆ SQL: [“ml\\_qa\\_triggersendreceive” on page 672](#)

### Automatic policy

The automatic policy attempts to keep the client and server message stores as up-to-date as possible.

When using the automatic policy, message transmission is performed when any of the following conditions occurs:

- ◆ PutMessage() is called.

For more information about PutMessage see:

- ◆ .NET: [“PutMessage method” on page 298](#)
- ◆ C++: [“putMessage function” on page 452](#)
- ◆ Java: [“getStringStoreProperty method” on page 557](#)
- ◆ SQL: [“ml\\_qa\\_putmessage” on page 672](#)

- ◆ A message status changes has occurred. This typically occurs when a received message is acknowledged by the application.

For more information about acknowledgement, see:

- ◆ .NET: [“AcknowledgementMode enumeration” on page 244](#)
- ◆ C++: [“AcknowledgementMode class” on page 392](#)
- ◆ Java: [“Interface AcknowledgementMode” on page 504](#)
- ◆ SQL: all messaging using the SQL API is transactional

- ◆ A Push Notification is received.

For more information about push notifications, see [“Using push notifications” on page 41](#).

- ◆ A Network Status Change Notification is received.

For more information, see [“Notifications of push notification” on page 53](#).

- ◆ TriggerSendReceive() is called.

For more information about TriggerSendReceive, see:

- ◆ .NET: [“TriggerSendReceive method” on page 309](#)
- ◆ C++: [“triggerSendReceive function” on page 461](#)
- ◆ Java: [“setStringStoreProperty method” on page 564](#)
- ◆ SQL: [“ml\\_qa\\_triggersendreceive” on page 672](#)

### Ondemand policy

The ondemand policy causes message transmission to occur only when instructed to do so by an application.

An application forces a message transmission to occur by calling TriggerSendReceive().

When the agent receives a Push Notification or a Network Status Change Notification, a corresponding message is sent to the system queue. This allows an application to detect these events and force a message transmission by calling TriggerSendReceive().

☞ For more information about TriggerSendReceive, see:

- ◆ .NET: [“TriggerSendReceive method” on page 309](#)
- ◆ C++: [“triggerSendReceive function” on page 461](#)
- ◆ Java: [“setStringStoreProperty method” on page 564](#)
- ◆ SQL: [“ml\\_qa\\_triggersendreceive” on page 672](#)

☞ For more information about handling push notifications and network status changes, see [“System queue” on page 51](#).

### Custom policy

A custom policy allows you to define when message transmission occurs and which messages to send in the message transmission. The custom policy is defined by a set of transmission rules.

Each rule is of the following form:

*schedule* = *condition*

where *schedule* defines when *condition* is evaluated. For more information, see [“Rule syntax” on page 226](#).

All messages satisfying *condition* are transmitted. In particular, if *schedule* is automatic, the condition is evaluated when any of the following conditions occurs:

- ◆ PutMessage() is called.

For more information about PutMessage, see:

- ◆ .NET: [“PutMessage method” on page 298](#)
- ◆ C++: [“putMessage function” on page 452](#)
- ◆ Java: [“getStringStoreProperty method” on page 557](#)
- ◆ SQL: [“ml\\_qa\\_putmessage” on page 672](#)
- ◆ A message status change has occurred. This typically occurs when a message is acknowledged by the application.

For more information about acknowledgement, see:

- ◆ .NET: [“AcknowledgementMode enumeration” on page 244](#)
- ◆ C++: [“AcknowledgementMode class” on page 392](#)
- ◆ Java: [“Interface AcknowledgementMode” on page 504](#)
- ◆ SQL: all messaging using the SQL API is transactional
- ◆ A Push Notification is received.

For more information about push notifications, see [“Using push notifications” on page 41](#).

- ◆ A Network Status Change Notification is received.

- ◆ TriggerSendReceive ( ) is called.

For more information about TriggerSendReceive, see:

- ◆ .NET: [“TriggerSendReceive method” on page 309](#)
- ◆ C++: [“triggerSendReceive function” on page 461](#)
- ◆ Java: [“setStringStoreProperty method” on page 564](#)
- ◆ SQL: [“ml\\_qa\\_triggersendreceive” on page 672](#)

☞ For more information about transmission rules, see [“Message transmission rules” on page 234](#).

☞ For more information about creating policies, see [“-policy option” on page 163](#).

## Using push notifications

A push notification is a special message delivered from the server message store to a QAnywhere client that prompts the client to initiate a message transmission. Push notification is on by default but is optional. Push notifications introduce extra components to the QAnywhere architecture:

- ◆ At the server, a QAnywhere Notifier sends push notifications.
- ◆ At the client, a QAnywhere Listener receives these push notifications and passes them on to the QAnywhere Agent.
- ◆ At the client, a notification of each push notification is sent to the system queue.

If you use the scheduled or automatic QAnywhere Agent policies, push notifications automatically cause clients to initiate message transmission. If you use the ondemand policy, you must handle push requests manually using an event handler.

☞ For more information about manually handling push notifications, see [“Notifications of push notification” on page 53](#).

☞ For more information about QAnywhere Agent policies, see [“Determining when message transmission should occur on the client” on page 36](#).

Push notifications are enabled by default: the qaagent -push option is by default set to connected. In connected mode, push notifications are sent over TCP/IP persistent connection.

If you are using UDP, push notifications are likely to work without any configuration, but due to a limitation in the UDP implementation of ActiveSync, they will not work with ActiveSync.

- ◆ [“Notifications of push notification” on page 53](#)
- ◆ [“-push option” on page 165](#)

## Setting up a failover mechanism

QAnywhere applications can be set up with a failover mechanism so that alternate MobiLink servers can be used if one fails. In order to support failover, each QAnywhere Agent must be started with a list of MobiLink servers. The first MobiLink server specified in the list is the primary server. The remaining servers in the list are alternate servers.

For example, running the following command on the remote device will start the QAnywhere Agent with one primary server and one alternate server:

```
qaagent -x tcpip(host=ml1.ianywhere.com)
        -x tcpip(host=ml2.ianywhere.com)
```

Each QAnywhere Agent can have a different primary server.

The following diagram describes a failover configuration in which you have multiple MobiLink servers and multiple QAnywhere agents. You have multiple client message stores, but all MobiLink servers are connected to the same server-side message store.

This configuration has the following characteristics:

- ◆ When a message transmission occurs, all messages in the server message store are delivered to the client message store regardless of the server that the QAnywhere Agent is connected to.
- ◆ Push Notifications are sent to a QAnywhere Agent only when the QAnywhere Agent is connected to its primary server.
- ◆ There is a single point of failure. If the machine with the server message store is unavailable, no messaging can take place.

By default, when you set up failover MobiLink servers, the QAnywhere Agent always tries an alternate server immediately upon a failure to reach the primary server. If you want to change this default behavior, you can use the QAnywhere Agent `-fr` option to cause the QAnywhere Agent to try the primary server again before going to the alternate server, and to specify the number of times it should retry. You can use the `-fd` option to specify the amount of time between retries of the primary server.

The `-fr` and `-fd` options apply only to the primary server. If a connection to the primary server cannot be established after the specified number of attempts, the QAnywhere Agent tries to connect to an alternate server. The Agent attempts to connect to each alternate server only once. An error is issued if the Agent cannot establish a connection to an alternate server.

### About this chapter

This chapter describes how to write QAnywhere client applications.

## Introduction to the QAnywhere interfaces

QAnywhere client applications manage the receiving and sending of QAnywhere messages. The applications can be written using one of several QAnywhere APIs:

- ◆ QAnywhere .NET API
- ◆ QAnywhere C++ API
- ◆ QAnywhere Java API
- ◆ QAnywhere SQL API

You can use a combination of client types in your QAnywhere system. For example, messages that are generated using QAnywhere SQL can also be received by a client created using the APIs for .NET, C++, or Java. If you have configured a JMS connector on your server, the messages can also be received by JMS clients. Similarly, QAnywhere SQL can be used to receive messages that were generated by QAnywhere .NET, C++, Java, or JMS clients.

### QAnywhere .NET API

The QAnywhere .NET API is a programming interface for deployment to Windows computers using the Microsoft .NET Framework and to handheld devices running the Microsoft .NET Compact Framework. The QAnywhere .NET API is provided as the `iAnywhere.QAnywhere.Client` namespace.

QAnywhere supports Microsoft Visual Studio .NET 2003 and 2005.

#### Note

In this document, code samples for the .NET API use the C# programming language, but the API can be accessed using any programming language that Microsoft .NET supports.

Versions of the TestMessage sample application are written in Java, C#, and Visual Basic.NET. There is also a .NET compact framework sample.

☞ For more information about the .NET version of the TestMessage sample application, see [“Lesson 4: Explore the TestMessage client source code” on page 23](#).

☞ For more information about the QAnywhere .NET API, see [“iAnywhere.QAnywhere.Client namespace \(.NET\)” on page 244](#).

### QAnywhere C++ API

The QAnywhere C++ API supports Microsoft Visual C++ 6.0, Microsoft Visual Studio .NET 2003, Microsoft eMbedded Visual C++ 3.0, Microsoft eMbedded Visual C++ 4.0, and Visual Studio 2005.

The QAnywhere C++ API consists of the following files:

- ◆ A set of header files (the main one being `qa.hpp`) located in the `QAnywhere\h` subdirectory of your SQL Anywhere installation.

- ◆ An import library (*qany10.lib*) located in the `\ce\arm.30\lib`, `\ce\arm.50\lib`, `QAnywhere\lib`, and `ce\x86.30\lib` subdirectories of your SQL Anywhere installation.
- ◆ A run-time DLL (*qany10.dll*) located in the `win32`, `ce\arm.30`, and `ce\x86.30` subdirectories of your SQL Anywhere installation.

Your source code file must include the header file in order to access the API. The import library is used to link your application to the run-time DLL. The run-time DLL must be deployed with your application.

A version of the TestMessage sample application written in C++ is supplied in `samples-dir\QAnywhere`. (For information about `samples-dir`, see “[The samples directory](#)” [*SQL Anywhere Server - Database Administration*].)

☞ For more information about the QAnywhere C++ API, see “[QAnywhere C++ API Reference](#)” on page 391.

### QAnywhere Java API

The QAnywhere Java API supports JRE 1.4.2 and 1.5.0.

The QAnywhere Java API consists of the following files:

- ◆ API reference material, available in this book or in Javadoc format in the `\docs\javadocs\QAnywhere` subdirectory of your SQL Anywhere 10 installation.
- ◆ Runtime DLLs (*qany10jni.dll* and *qany10.dll*), located in the `win32` subdirectory of your SQL Anywhere 10 installation.
- ◆ An archive of the class files (*qaclient.jar*), located in the `java` subdirectory of your SQL Anywhere 10 installation.

The class file archive must be included in your path when you compile your application. The run-time DLLs must be deployed with your application.

A version of the TestMessage sample application written in Java is supplied in `samples-dir\QAnywhere\Desktop\J2SE`. (For information about `samples-dir`, see “[The samples directory](#)” [*SQL Anywhere Server - Database Administration*].)

☞ For more information about the QAnywhere Java API, see “[QAnywhere Java API Reference](#)” on page 503.

### QAnywhere SQL API

The QAnywhere SQL API is a set of stored procedures that implement a messaging API in SQL. Using the QAnywhere SQL API, you can create messages, set or get message properties and content, send and receive messages, trigger message synchronization, and set and get message store properties.

☞ For more information about QAnywhere SQL, see “[QAnywhere SQL API Reference](#)” on page 635.

### **JMS connector**

QAnywhere includes a JMS connector that provides connectivity between QAnywhere and JMS applications.

For more information, see:

- ◆ [“Scenario for messaging with external messaging systems” on page 11](#)
- ◆ [“Introduction” on page 128](#)
- ◆ [“Tutorial: Using JMS connectors” on page 141](#)

### **Mobile web services connector**

QAnywhere includes a mobile web services connector for messaging between QAnywhere and web services.

☞ For more information, see [“Mobile Web Services” on page 181](#).

## Overview of writing a client application

### ◆ To build a client application

1. Initialize the appropriate QAnywhere API. See:
  - ◆ [“Setting up .NET applications” on page 54](#)
  - ◆ [“Setting up C++ applications” on page 56](#)
  - ◆ [“Setting up Java applications” on page 58](#)
  - ◆ [“Setting up SQL applications” on page 59](#)
2. Set QAnywhere manager configuration properties. See [“QAnywhere manager configuration properties” on page 62](#).
3. Write application code and compile. See the following sections:
  - ◆ [“Message headers and message properties” on page 206](#)
  - ◆ [“Client message store properties” on page 215](#)
  - ◆ [“Sending QAnywhere messages” on page 66](#)
  - ◆ [“Receiving QAnywhere messages” on page 75](#)
  - ◆ [“Reading very large messages” on page 80](#)
  - ◆ [“Implementing transactional messaging” on page 68](#)
  - ◆ [“Shutting down QAnywhere” on page 88](#)
4. Deploy the application to the target device.
  - ☞ See [“Deploying QAnywhere applications” on page 89](#).

## QAnywhere message addresses

A QAnywhere message destination has two parts, the client message store ID and the application queue name:

*id\queue-name*

The queue name is specified inside the application, and must be known to instances of the sending application on other devices. For information about client message store IDs, see [“Setting up the client message store” on page 33](#).

When constructing addresses as strings in an application, be sure to escape the backslash character if necessary. Follow the string escaping rules for the programming language you are using. If your JMS destination contains a backslash, you must escape it with another backslash.

### System queue

Notifications and network status changes are both sent to QAnywhere applications as **system messages**. System messages are the same as other messages, but are received in a separate queue named **system**.

☞ See [“System queue” on page 51](#).

### Sending a message to a JMS connector

A QAnywhere-to-JMS destination address has two parts:

- ◆ The connector address. This is the value of the `ianywhere.connector.address` property.

For more information, see [“JMS connector properties” on page 132](#).

- ◆ The JMS queue name. This is a queue that you create using your JMS administration tools.

The form of the destination address is:

*connector-address\JMS-queue-name*

For more information about addressing messages in a JMS application, see:

- ◆ [“Addressing QAnywhere messages meant for JMS” on page 137](#)
- ◆ [“Addressing JMS messages meant for QAnywhere” on page 139](#)
- ◆ [“JMS Connectors” on page 127](#)

### Destination aliases

A **destination alias** is a list of message addresses and other destination aliases. When a message is sent to a destination alias, it is sent to all members of the list.

A member of a destination alias can have a delivery condition associated with it. Only messages that match the condition are forwarded to the corresponding member.

## Example

Define a destination alias called `all_clients` with members `client1` and `client2`.

Define the following delivery condition for `client1`:

```
ias_Priority=1
```

Define the following delivery condition for `client2`:

```
ias_Priority=9
```

Only messages with priority 1 are sent to `client1` and those with priority 9 are sent to `client2`.

## Creating destination aliases

You can create and manage a destination alias using the following methods:

- ◆ Server management requests

See [“Creating destination aliases using server management requests” on page 117](#).

- ◆ Sybase Central

See [“Creating destination aliases using Sybase Central” on page 51](#).

## Creating destination aliases using Sybase Central

You can use Sybase Central to create or modify a destination alias.

### ◆ To create a destination alias using Sybase Central

1. Start Sybase Central:
  - ◆ Choose **Start** ► **Programs** ► **SQL Anywhere 10** ► **Sybase Central**.
  - ◆ Choose **Connections** ► **Connect to QAnywhere 10**.
  - ◆ Specify an ODBC data source name or file, and a user ID and password if required.
  - ◆ Click **OK**.
2. Choose **File** ► **New** ► **Destination Alias**.
3. In the **Alias** field, type a name for the alias.
4. In the **Destinations** field, type the name of each destination on its own line.
5. Click **OK**.

## System queue

A special queue called **system** exists to receive QAnywhere system messages. There are two types of message that are sent to the system queue:

- ◆ [“Network status notifications” on page 52](#)
- ◆ [“Notifications of push notification” on page 53](#)

### Example

The following C# code processes system and normal messages and can be useful if you are using an ondemand policy. It assumes that you have defined the message handling methods `onMessage()` and `onSystemMessage()` that implement the application logic for processing the messages.

```
// Declare the message listener and system listener.
private QAManager.MessageListener _receiveListener;
private QAManager.MessageListener _systemListener;
...

// Create a MessageListener that uses the appropriate message handlers.
_receiveListener = new QAManager.MessageListener( onMessage );
_systemListener = new QAManager.MessageListener( onSystemMessage );
...

// Register the message handler.
mgr.SetMessageListener( queue-name, _receiveListener );
mgr.SetMessageListener( "system", _systemListener );
```

The system message handler may query the message properties to identify what information it contains. The message type property indicates if the message holds a network status notification. For example, for a message `msg`, you could perform the following processing:

```
msg_type = (MessageType)msg.GetIntProperty( MessageProperties.MSG_TYPE );
if( msg_type == MessageType.NETWORK_STATUS_NOTIFICATION ) {
    // Process a network status change.
    mgr.TriggerSendReceive( );
} else if ( msg_type == MessageType.PUSH_NOTIFICATION ) {
    // Process a push notification.
    mgr.TriggerSendReceive( );
} else if ( msg_type == MessageType.REGULAR ) {
    // This message type should not be received on the
    // system queue. Take appropriate action here.
}
```

### Network status notifications

When there is a change in network status, a message of type `NETWORK_STATUS_NOTIFICATION` is sent to the system queue. It has an expiry of one minute. This expiry time cannot be changed.

When a device goes into network coverage or out of network coverage, a message is sent to the system queue that contains the following information:

- ◆ **ias\_Adapters** String. A list of network adapters that can be used to connect to the MobiLink server. The list is delimited by a vertical bar. This property can be read but should not be set.

For more information, see:

- ◆ .NET: [“ADAPTER field” on page 246](#)
- ◆ C++: [“ADAPTER variable” on page 395](#)

- ◆ Java: [“ADAPTERS variable” on page 507](#)
- ◆ **ias\_RASNames** String. A list of network names that can be used to connect to the MobiLink server. The list is delimited by a vertical bar.

For more information, see:

- ◆ .NET: [“RASNAMES field” on page 251](#)
- ◆ Java: [“RASNAMES variable” on page 509](#)
- ◆ C++: [“RASNAMES variable” on page 399](#)
- ◆ **ias\_NetworkStatus** Int. The state of the network connection. The value is 1 if connected, 0 otherwise.

For more information, see:

- ◆ .NET: [“NETWORK\\_STATUS field” on page 249](#)
- ◆ Java: [“NETWORK\\_STATUS variable” on page 508](#)
- ◆ C++: [“NETWORK\\_STATUS variable” on page 397](#)

### Monitoring network availability

You can use network status notifications to monitor network availability and take action when a device comes into coverage. For example, use the ondemand policy and call `QAManagerBase triggerSendReceive` when a system queue message is received of type `NETWORK_STATUS_NOTIFICATION` with `ias_NetworkStatus=1`.

### See also

- ◆ `ias_MessageType` in [“Pre-defined message properties” on page 209](#)
- ◆ [“System queue” on page 50](#)

### Notifications of push notification

A message of type `PUSH_NOTIFICATION` is sent to the system queue when a push notification is received from the server. This message is a notification that messages are queued on the server. It has an expiry of one minute. This expiry time cannot be changed.

This type of system message is useful if you are using the ondemand policy. For example, you can call `QAManagerBase triggerSendReceive` when a system queue message is received of type `PUSH_NOTIFICATION`.

### See also

- ◆ [“Scenario for messaging with push notifications” on page 9](#)
- ◆ [“Using push notifications” on page 41](#)
- ◆ [“System queue” on page 50](#)
- ◆ [“Receiving messages asynchronously” on page 76](#)
- ◆ `ias_MessageType` in [“Pre-defined message properties” on page 209](#)
- ◆ .NET: [“MessageProperties class” on page 245](#)
- ◆ C++: [“MessageProperties class” on page 394](#)
- ◆ Java: [“Interface MessageProperties” on page 505](#)

## Initializing a QAnywhere API

Before you can send or receive messages using QAnywhere, you must complete the following initialization tasks.

### Setting up .NET applications

Before you can send or receive messages using QAnywhere .NET clients, you must complete the following initialization tasks.

You must make two changes to your Visual Studio .NET project to be able to use it:

- ◆ Add a reference to the QAnywhere .NET DLL. Adding a reference tells Visual Studio.NET which DLL to include to find the code for the QAnywhere .NET API.
- ◆ Add a line to your source code to reference the QAnywhere .NET API classes. In order to use the QAnywhere .NET API, you must add a line to your source code to reference the data provider. You must add a different line for C# than for Visual Basic.NET.

In addition, you must initialize the QAnywhere .NET API.

#### ◆ To add a reference to the QAnywhere .NET API in a Visual Studio .NET project

1. Start Visual Studio .NET and open your project.
2. In the Solution Explorer window, right-click the References folder and choose Add Reference from the popup menu.

The Add Reference dialog appears.

3. On the .NET tab, click Browse to locate iAnywhere.QAnywhere.Client.dll. The default locations are (relative to your SQL Anywhere installation directory):

- ◆ .NET Framework 1.1: *\Assembly\1*
- ◆ .NET Framework 2.0: *\Assembly\2*
- ◆ .NET Compact Framework 1.0: *ce\Assembly\1*
- ◆ .NET Compact Framework 2.0: *ce\Assembly\2*

Select the DLL and click Open.

4. You can verify that the DLL is added to your project. Open the Add Reference dialog and then click the .NET tab. iAnywhere.QAnywhere.Client.dll appears in the Selected Components list. Click OK to close the dialog.

### Referencing the data provider classes in your source code

#### ◆ To reference the QAnywhere .NET API classes in your code

1. Start Visual Studio .NET and open your project.

2. If you are using C#, add the following line to the list of using directives at the beginning of your file:

```
using iAnywhere.QAnywhere.Client;
```

3. If you are using Visual Basic .NET, add the following line to the list of imports at the beginning of your file:

```
Imports iAnywhere.QAnywhere.Client
```

This line is not strictly required. However, it allows you to use short forms for the QAnywhere classes. Without it, you can still use the fully qualified class name in your code. For example:

```
iAnywhere.QAnywhere.Client.QAManager
mgr =
    new iAnywhere.QAnywhere.Client.QAManagerFactory.Instance.CreateQAManager
    (
        "qa_manager.props" );
```

instead of

```
QAManager mgr = QAManagerFactory.Instance.CreateQAManager(
    "qa_manager.props" );
```

#### ◆ To initialize the QAnywhere .NET API

1. Include the iAnywhere.QAnywhere.Client namespace, as described in the previous procedure.

```
using iAnywhere.QAnywhere.Client;
```

2. Create a QAManager object.

For example, to create a default QAManager object, invoke CreateQAManager with null as its parameter:

```
QAManager mgr;
mgr = QAManagerFactory.Instance.CreateQAManager( null );
```

#### Tip

For maximum concurrency benefits, multi-threaded applications should create a QAManager for each thread. See [“Multi-threaded QAManager” on page 61](#).

☞ For more information about QAManagerFactory, see [“QAManagerFactory class” on page 310](#).

You can alternatively create a QAManager object that is customized using a properties file. The properties file is specified in the CreateQAManager method:

```
mgr = QAManagerFactory.Instance.CreateQAManager(
    "qa_mgr.props" );
```

where *qa\_mgr.props* is the name of the properties file that resides on the remote device.

3. Initialize the QAManager object. For example:

```
mgr.Open(
    AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT );
```

The argument to the open method is an acknowledgement mode, which indicates how messages are to be acknowledged. It must be one of `IMPLICIT_ACKNOWLEDGEMENT` or `EXPLICIT_ACKNOWLEDGEMENT`. With implicit acknowledgement, messages are acknowledged as soon as they are received by the client. With explicit acknowledgement, you must call the acknowledgement method on the `QAManager` to acknowledge the message.

☞ For more information about acknowledgement modes, see [“AcknowledgementMode enumeration” on page 244](#).

You are now ready to send messages.

Instead of creating a `QAManager`, you can create a `QATransactionalManager`. See [“Implementing transactional messaging for .NET clients” on page 68](#).

### See also

- ◆ [“iAnywhere.QAnywhere.Client namespace \(.NET\)” on page 244](#)

## Setting up C++ applications

Before you can send or receive messages using QAnywhere C++ clients, you must complete the following initialization tasks.

### ◆ To initialize the QAnywhere C++ API

1. Include the QAnywhere header file.

```
#include <qa.hpp>
```

*qa.hpp* defines the QAnywhere classes.

2. Initialize QAnywhere.

To do this, initialize a factory for creating `QAManager` objects.

```
QAManagerFactory * factory;  
  
factory = QAnywhereFactory_init();  
if( factory == NULL ) {  
    // Fatal error.  
}
```

☞ For more information about `QAManagerFactory`, see [“QAManagerFactory class” on page 462](#).

3. Create a `QAManager` instance.

You can create a default `QAManager` object as follows:

```
QAManager * mgr;  
  
// Create a manager  
mgr = factory->createQAManager( NULL );
```

```
if( mgr == NULL ) {
    // fatal error
}
```

☞ For more information about QAManager, see [“QAManager class” on page 427](#).

**Tip**

For maximum concurrency benefits, multi-threaded applications should create a QAManager for each thread. See [“Multi-threaded QAManager” on page 61](#).

You can customize a QAManager object programmatically or using a properties file.

- ◆ To customize QAManager programmatically, use `setProperty()`.

For more information, see [“Setting QAnywhere manager configuration properties programmatically” on page 64](#).

- ◆ To use a properties file, specify the properties file in `createQAManager()`:

```
mgr = factory->createQAManager( "qa_mgr.props" );
```

where *qa\_mgr.props* is the name of the properties file on the remote device.

For more information, see [“Setting QAnywhere manager configuration properties in a file” on page 62](#).

4. Initialize the QAManager object.

```
qa_bool rc;
rc=mgr->open(
    AcknowledgementMode::IMPLICIT_ACKNOWLEDGEMENT );
```

The argument to the `open` method is an acknowledgement mode, which indicates how messages are to be acknowledged. It must be one of **IMPLICIT\_ACKNOWLEDGEMENT** or **EXPLICIT\_ACKNOWLEDGEMENT**. With implicit acknowledgement, messages are acknowledged as soon as they are received by the client. With explicit acknowledgement, you must call one of the acknowledge methods on the QAManager to acknowledge the message.

☞ For more information about acknowledgement modes, see [“AcknowledgementMode class” on page 392](#).

Instead of creating a QAManager, you can create a QATransactionalManager. See [“Implementing transactional messaging for C++ clients” on page 70](#).

You are now ready to send messages.

**See also**

- ◆ [“QAnywhere C++ API Reference” on page 391](#)

## Setting up Java applications

Before you can send or receive messages using QAnywhere Java clients, you must complete the following initialization tasks.

### ◆ To initialize the QAnywhere Java API

1. Add the location of *qaclient.jar* to your classpath. By default, it is located in the *java* subdirectory of your SQL Anywhere installation.
2. Import the `ianywhere.qanywhere.client` package.

```
import ianywhere.qanywhere.client.*;
```

3. Create a `QAManager` object.

```
QAManager mgr;  
mgr = QAManagerFactory.getInstance().createQAManager(null);
```

You can also customize a `QAManager` object by specifying a properties file to the `createQAManager` method:

```
mgr = QAManagerFactory.getInstance().createQAManager("qa_mgr.props.");
```

#### Tip

For maximum concurrency benefits, multi-threaded applications should create a `QAManager` for each thread. See [“Multi-threaded QAManager” on page 61](#).

4. Initialize the `QAManager` object.

```
mgr.open(AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT);
```

The argument to the `open` method is an acknowledgement mode, which indicates how messages are to be acknowledged. It must be one of `IMPLICIT_ACKNOWLEDGEMENT` or `EXPLICIT_ACKNOWLEDGEMENT`. With implicit acknowledgement, messages are acknowledged as soon as they are received by the client. With explicit acknowledgement, you must call one of the acknowledge methods on the `QAManager` to acknowledge the message.

☞ For more information about acknowledgement modes, see [“Interface AcknowledgementMode” on page 504](#).

Instead of creating a `QAManager`, you can create a `QATransactionalManager`. See [“Implementing transactional messaging for Java clients” on page 71](#).

You are now ready to send messages.

### See also

- ◆ [“QAnywhere Java API Reference” on page 503](#)

## Setting up SQL applications

QAnywhere SQL allows you to perform, in SQL, much of the messaging functionality of the QAnywhere .NET, C++, and Java APIs. This functionality includes creating messages, setting or getting message properties and content, sending and receiving messages, triggering message synchronization, and setting and getting message store properties.

Messages that are generated with QAnywhere SQL can also be received by clients created with the programming APIs. If you have configured a JMS connector on your server, the messages can also be received by JMS clients. Similarly, QAnywhere SQL can be used to receive messages that were generated by QAnywhere .NET, C++, or Java API, or JMS clients.

QAnywhere SQL messaging coexists with user transactions. This means that committing a transaction commits all the QAnywhere operations on that connection.

☞ For more information about QAnywhere applications, see [“Writing QAnywhere Client Applications”](#) on page 45.

### Permissions

Only users with DBA privilege have automatic permission to execute the QAnywhere stored procedures. To give permission to a user, a user with DBA privilege must call the procedure `ml_qa_grant_messaging_permissions`.

☞ See [“ml\\_qa\\_grant\\_messaging\\_permissions”](#) on page 670.

### Acknowledgement modes

The QAnywhere SQL API does not support `IMPLICIT_ACKNOWLEDGEMENT` or `EXPLICIT_ACKNOWLEDGEMENT` modes. All messaging through the SQL API is transactional.

### Example

The following example creates a trigger on an inventory table. The trigger sends a message when the inventory for an item falls below a certain threshold. The message is sent after the transaction invoking the trigger is committed. If the transaction is rolled back, the message is not sent.

```
CREATE TRIGGER inventory_trigger AFTER UPDATE ON inventory
REFERENCING old AS oldinv new AS newinv
FOR EACH ROW
begin
  DECLARE msgid VARCHAR(128);
  IF oldinv.quantity > newinv.quantity AND newinv.quantity < 10 THEN
    -- Create the message
    SET msgid = ml_qa_createmessage();
    -- Set the message content
    CALL ml_qa_settextcontent( msgid,
      'Inventory of item ' || newinv.itemname
      || ' has fallen to only ' || newinv.quantity );
    -- Make the message high priority
    CALL ml_qa_setpriority( msgid, 9 );
    -- Set a message subject
    CALL ml_qa_setstringproperty( msgid,
      'tm_Subject', 'Inventory low!' );
    -- Send the message to the inventoryManager queue
    CALL ml_qa_putmessage( msgid,
```

```
        'inventoryManager' );  
    end if;  
end
```

## Multi-threaded QAManager

Access to a QAManager is serialized. When you have multiple threads accessing a single QAManager, threads will block while one thread performs a method call on the QAManager. Use a different QAManager for each thread in order to maximize concurrency. Only one thread is allowed to access an instance of QAManager at one time. Other threads will block until the QAManager method that was invoked by the first thread returns.

## QAnywhere manager configuration properties

You can set QAnywhere manager configuration properties in one of the following ways:

- ◆ Create a properties text file to define the QAnywhere manager configuration properties that will be used by one Manager instance.

See “[Setting QAnywhere manager configuration properties in a file](#)” on page 62.

- ◆ Set QAnywhere manager configuration properties programmatically.

See “[Setting QAnywhere manager configuration properties programmatically](#)” on page 64.

Following are the QAnywhere manager configuration properties:

- ◆ **COMPRESSION\_LEVEL=n** Set the compression level.

*n* is the compression factor, which is expressed as is an integer between 0 and 9, where 0 indicates no compression and 9 indicates maximum compression.

- ◆ **CONNECT\_PARAMS=connect-string** Specify a connection string for the QAnywhere manager to use to connect to the message store database. Specify each connection option in the form *keyword=value* with multiple options separated by semi-colons.

The default is "eng=qanywhere;uid=ml\_qa\_user;pwd=qanywhere"

☞ For a list of options, see “[Connection parameters](#)” [*SQL Anywhere Server - Database Administration*].

☞ For information about managing the database user and password, see “[Writing Secure Messaging Applications](#)” on page 175.

- ◆ **LOG\_FILE=filename** Specify the name of a file to use to write logging messages. Specifying this option implicitly enables logging.
- ◆ **MAX\_IN\_MEMORY\_MESSAGE\_SIZE=n** When reading a message, *n* is the largest message, in bytes, for which a buffer is allocated. A message larger than *n* bytes must be read using streaming operations. The default value is 1MB on Windows and 64KB on Windows CE.

### Setting QAnywhere manager configuration properties in a file

The information in a QAnywhere manager properties file is specific to one instance of a QAManager.

When using a properties file, it must be configured for and installed on the remote device with each deployed copy of your application.

For information on specifying the name of the property file, see:

- ◆ .NET API: “[CreateQAManager method](#)” on page 313

- ◆ C++ API: [“createQAManager function” on page 462](#)
- ◆ Java API: [“createQAManager method” on page 568](#)
- ◆ SQL API: You cannot set properties in a file using the QAnywhere SQL API. See [“Setting QAnywhere manager configuration properties programmatically” on page 64](#).

If the properties file does not reside in the same directory as your client executable, you must also specify the absolute path. If you want to use the default settings for the properties, use NULL instead of a file name.

Values set in the file permit you to enable or disable some of the QAnywhere features, such as automatic message compression and logging.

Entries in a QAnywhere manager configuration properties file take the form *name=value*. For a list of property names, see [“QAnywhere manager configuration properties” on page 62](#). If *value* has spaces, enclose it in double-quotes. Comment lines start with #. For example:

```
# contents of QAnywhere manager configuration properties file
LOG_FILE=.\sender.ini.txt
# A comment
CONNECT_PARAMS=eng=qanywhere;uid=ml_qa_user;pwd=qanywhere
MAX_IN_MEMORY_MESSAGE_SIZE=2048
COMPRESSION_LEVEL=0
```

## Referencing the configuration file

Suppose you have a QAnywhere manager configuration properties file called *mymanager.props* with the following content:

```
COMPRESSION_LEVEL=9
CONNECT_PARAMS=DBF=mystore.db
```

When you create QAManager, you reference the file by name.

Following is an example using C#:

```
QAManager mgr;
mgr = QAManagerFactory.Instance.CreateQAManager( "mymanager.props" );
mgr.Open( AcknowledgeMode.EXPLICIT_ACKNOWLEDGEMENT );
```

☞ For more information, see [“QAManager interface” on page 271](#) and [“QAManagerFactory class” on page 310](#) in the QAnywhere .NET API reference.

Following is an example using C++:

```
QAManagerFactory * qa_factory;
QAManager * mgr;
qa_factory = QAnywhereFactory_init();
qa_factory->createQAManager( "mymanager.props" );
mgr->open( AcknowledgementMode::EXPLICIT_ACKNOWLEDGEMENT );
```

☞ For more information, see [“QAManager class” on page 427](#) and [“QAManagerFactory class” on page 462](#) in the QAnywhere C++ API reference.

Following is an example using Java:

```
QAManager mgr;  
mgr = QAManagerFactory.getInstance().createQAManager( "mymanager.props" );  
mgr.open( AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT );
```

☞ For more information, see [“Class QAManagerFactory” on page 566](#) and [“Interface QAManager” on page 536](#) in the QAnywhere Java API reference.

## Setting QAnywhere manager configuration properties programmatically

In the QAnywhere APIs, you can use the QAManagerBase set property method to set properties programmatically. Setting QAnywhere manager configuration properties programmatically must be done before calling the open method of a QAManager instance.

☞ For more information about QAManagerProperties, see [“QAnywhere manager configuration properties” on page 62](#).

### Example

The following C# example sets properties programmatically. When you create the QAManager, you specify the property settings.

```
QAManager mgr;  
mgr = QAManagerFactory.Instance.CreateQAManager( null );  
mgr.SetProperty( "COMPRESSION_LEVEL", "9" );  
mgr.SetProperty( "CONNECT_PARAMS", "DBF=mystore.db" );  
mgr.Open( AcknowledgeMode.EXPLICIT_ACKNOWLEDGEMENT );
```

☞ For more information, see [“QAManager interface” on page 271](#) and [“QAManagerFactory class” on page 310](#) in the QAnywhere .NET API reference.

The following C++ example sets properties programmatically. When you create the QAManager, you specify the property settings.

```
QAManagerFactory * qa_factory;  
QAManager * mgr;  
qa_factory = QAnywhereFactory_init();  
mgr = qa_factory->createQAManager( NULL );  
mgr->setProperty( "COMPRESSION_LEVEL", "9" );  
mgr->setProperty( "CONNECT_PARAMS", "DBF=mystore.db" );  
mgr->open( AcknowledgementMode::EXPLICIT_ACKNOWLEDGEMENT );
```

☞ For more information, see [“QAManager class” on page 427](#) and [“QAManagerFactory class” on page 462](#) in the QAnywhere C++ API reference.

The following Java example sets properties programmatically. When you create the QAManager, you specify the property settings.

```
QAManager mgr;  
mgr = QAManagerFactory.getInstance().createQAManager( null );  
mgr.setProperty( "COMPRESSION_LEVEL", 9 );  
mgr.setStringProperty( "CONNECT_PARAMS", "DBF=mystore.db" );  
mgr.open( AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT );
```

☞ For more information, see [“Class QAManagerFactory” on page 566](#) and [“Interface QAManager” on page 536](#) in the QAnywhere Java API reference.

## Sending QAnywhere messages

The following procedures describe how to send messages from QAnywhere applications. These procedures assume that you have created and opened a QAManager object.

Sending a message from your application does not ensure it is delivered from your device. It simply places the message on a queue to be delivered. The QAnywhere Agent carries out the task of sending the message to the MobiLink server, which in turn delivers it to its destination.

☞ For more information about when message transmission occurs, see [“Determining when message transmission should occur on the client” on page 36](#).

### ◆ To send a message (.NET)

1. Create a new message.

You can create either a text message or a binary message, using `CreateTextMessage()` or `CreateBinaryMessage()`, respectively.

```
QATextMessage    msg;  
msg = mgr.CreateTextMessage();
```

2. Set message properties.

Use methods of the `QATextMessage` or `QABinaryMessage` class to set properties.

☞ For more information, see [“Message headers and message properties” on page 206](#).

3. Put the message on the queue, ready for sending.

```
mgr.PutMessage( "store-id\\queue-name", msg );
```

where *store-id* and *queue-name* are strings that combine to form the destination address.

☞ For more information, see [“PutMessage method” on page 298](#) in the .NET API.

☞ For more information about determining when a message is transmitted, see [“Determining when message transmission should occur on the client” on page 36](#).

### ◆ To send a message (C++)

1. Create a new message.

You can create either a text message or a binary message, using `createTextMessage()` or `createBinaryMessage()`, respectively.

```
QATextMessage *  msg;  
msg = mgr->createTextMessage();
```

2. Set message properties.

Use methods of the `QATextMessage` or `QABinaryMessage` class to set message properties.

☞ For more information, see [“Message headers and message properties”](#) on page 206.

3. Put the message on the queue, ready for sending.

```
if( msg != NULL ) {
    if( !mgr->putMessage( "store-id\\queue-name", msg ) ) {
        // Display error using mgr->getLastErrorMsg().
    }
    mgr->deleteMessage( msg );
}
```

where *store-id* and *queue-name* are strings that combine to form the destination address.

☞ For more information, see [“putMessage function”](#) on page 452 in the C++ API.

☞ For more information about determining when a message is transmitted, see [“Determining when message transmission should occur on the client”](#) on page 36.

#### ◆ To send a message (Java)

1. Create a new message.

You can create a text message or a binary message, using `QAManagerBase.createTextMessage()` or `QAManagerBase.createBinaryMessage()`, respectively.

```
QATextMessage msg;
msg = mgr.createTextMessage();
```

2. Set message properties.

Use `QATextMessage` or `QABinaryMessage` methods to set message properties.

☞ For more information, see [“Message headers and message properties”](#) on page 206.

3. Put the message on the queue.

```
mgr.putMessage( "store-id\\queue-name", msg );
```

☞ For more information, see [“getStringStoreProperty method”](#) on page 557 in the Java API.

☞ For more information about determining when a message is transmitted, see [“Determining when message transmission should occur on the client”](#) on page 36.

#### ◆ To send a message (SQL)

1. Declare a variable to hold the message ID.

```
begin
    declare @msgid varchar(128);
```

2. Create a new message.

```
set @msgid = ml_qa_createmessage();
```

3. Set message properties.

☞ For more information, see [“Message properties” on page 645](#).

4. Put the message on the queue.

```
call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
commit;
end
```

☞ For more information, see [“ml\\_qa\\_putmessage” on page 672](#).

For more information about determining when a message is transmitted, see [“Determining when message transmission should occur on the client” on page 36](#).

## Implementing transactional messaging

Transactional messaging provides the ability to group messages in a way that guarantees that either all messages in the group are delivered, or none are. This is more commonly referred to as a single **transaction**.

When implementing transactional messaging, you create a special QAManagerBase object called QATransactionalManager.

For more information, see:

- ◆ .NET clients: [“QATransactionalManager interface” on page 337](#)
- ◆ C++ clients: [“QATransactionalManager class” on page 492](#)
- ◆ Java clients: [“Interface QATransactionalManager” on page 594](#)
- ◆ SQL clients: all messaging is transactional for SQL clients and no transactional manager is required

## Implementing transactional messaging for .NET clients

### ◆ To create a transactional manager

1. Initialize QAnywhere.

This step is the same as in non-transactional messaging.

```
using iAnywhere.QAnywhere.Client;
```

2. Create a QATransactionalManager object.

For example, to create a default QATransactionalManager object, invoke CreateQATransactionalManager with null as its parameter:

```
QAManager mgr;
mgr =
    QAManagerFactory.Instance.CreateQATransactionalManager(
        null );
```

☞ For more information about QAManagerFactory, see [“QAManagerFactory class” on page 310](#).

You can alternatively create a `QATransactionalManager` object that is customized using a properties file. The properties file is specified in the `CreateQATransactionalManager` method:

```
mgr =
    QAManagerFactory.Instance.CreateQATransactionalManager(
        "qa_mgr.props" );
```

where `qa_mgr.props` is the name of the properties file that resides on the remote device.

3. Initialize the `QAManager` object.

```
mgr.Open();
```

You are now ready to send messages. The following procedure sends two messages in a single transaction.

#### ◆ To send multiple messages in a single transaction

1. Initialize message objects.

```
QATextMessage msg_1;
QATextMessage msg_2;
```

2. Send the messages.

The following code sends two messages in a single transaction:

```
msg_1 = mgr.CreateTextMessage();
if( msg_1 != null ) {
    msg_2 = mgr.CreateTextMessage();
    if( msg_2 != null ) {
        if( !mgr.PutMessage( "jms_1\\queue_name", msg_1 ) ) {
            // Display message using mgr.GetLastErrorMsg().
        } else {
            if( !mgr.PutMessage( "jms_1\\queue_name", msg_2 ) ) {
                // Display message using mgr.GetLastErrorMsg().
            } else {
                mgr.Commit();
            }
        }
    }
}
```

The `Commit` method commits the current transaction and begins a new transaction. This method commits all `PutMessage()` method and `GetMessage()` method invocations.

#### Note

The first transaction begins with the call to open method.

#### See also

- ◆ [“QATransactionalManager interface” on page 337](#)

## Implementing transactional messaging for C++ clients

### ◆ To create a transactional manager

1. Initialize QAnywhere.

This step is the same as in non-transactional messaging.

```
#include <qa.hpp>
QAManagerFactory * factory;

factory = QAnywhereFactory_init();
if( factory == NULL ) {
    // Fatal error.
}
```

2. Create a transactional manager.

```
QATransactionalManager * mgr;
mgr = factory->createQATransactionalManager( NULL );
if( mgr == NULL ) {
    // Fatal error.
}
```

As with non-transactional managers, you can specify a properties file to customize QAnywhere behavior. In this example, no properties file is used.

3. Initialize the manager.

```
if( !mgr->open() ) {
    // Display message using mgr->getLastErrorMsg().
}
```

You are now ready to send messages. The following procedure sends two messages in a single transaction.

### ◆ To send multiple messages in a single transaction

1. Initialize message objects.

```
QATextMessage * msg_1;
QATextMessage * msg_2;
```

2. Send the messages.

The following code sends two messages in a single transaction:

```
msg_1 = mgr->createTextMessage();
if( msg_1 != NULL ) {
    msg_2 = mgr->createTextMessage();
    if( msg_2 != NULL ) {
        if( !mgr->putMessage( "jms_1\\queue_name", msg_1 ) ) {
            // Display message using mgr->getLastErrorMsg().
        } else {
            if( !mgr->putMessage( "jms_1\\queue_name", msg_2 ) ) {
                // Display message using mgr->getLastErrorMsg().
            } else {
                mgr->commit();
            }
        }
    }
    mgr->deleteMessage( msg_2 );
}
```

```

    }
    mgr->deleteMessage( msg_1 );
}

```

The commit method commits the current transaction and begins a new transaction. This method commits all putMessage() method and getMessage() method invocations.

**Note**

The first transaction begins with the call to open method.

**See also**

- ◆ C++: [“QATransactionalManager class” on page 492](#)
- ◆ Java: [“Interface QATransactionalManager” on page 594](#)

## Implementing transactional messaging for Java clients

### ◆ To create a transactional manager

1. Initialize QAnywhere.

This step is the same as in non-transactional messaging.

```

import ianywhere.qanywhere.client;
QAManagerFactory factory = new QAManagerFactory();

```

 For more information about QAManagerFactory, see [“QAManagerFactory class” on page 310](#).

2. Create a QATransactionalManager object.

For example, to create a default QATransactionalManager object, invoke createQATransactionalManager with null as its parameter:

```

QAManager mgr;
mgr = factory.createQATransactionalManager( null );

```

You can alternatively create a QATransactionalManager object that is customized using a properties file. The properties file is specified in the createQATransactionalManager method:

```

mgr = factory.createQATransactionalManager( "qa_mgr.props" );

```

where *qa\_manager.props* is the name of the properties file that resides on the remote device.

3. Initialize the QAManager object.

```

mgr.open();

```

You are now ready to send messages. The following procedure sends two messages in a single transaction.

### ◆ To send multiple messages in a single transaction

1. Initialize message objects.

```
QATextMessage msg_1;  
QATextMessage msg_2;
```

2. Send the messages.

The following code sends two messages in a single transaction:

```
msg_1 = mgr.createTextMessage();  
if( msg_1 != null ) {  
    msg_2 = mgr.createTextMessage();  
    if( msg_2 != null ) {  
        if( !mgr.putMessage( "jms_1\\queue_name", msg_1 ) ) {  
            // Display message using mgr.getLastErrMsg().  
        } else {  
            if( !mgr.putMessage( "jms_1\\queue_name", msg_2 ) ) {  
                // Display message using mgr.getLastErrMsg().  
            } else {  
                mgr.commit();  
            }  
        }  
    }  
}
```

The commit method commits the current transaction and begins a new transaction. This method commits all putMessage() method and getMessage() method invocations.

**Note**

The first transaction begins with the call to open method.

## Cancelling QAnywhere messages

Cancelling a QAnywhere message puts the message into a cancelled state before it is transmitted. With the default delete rules of the QAnywhere Agent, cancelled messages are eventually deleted from the message store. Cancelling a QAnywhere message fails if the message is already in a final state, or if it has been transmitted to the central messaging server.

The following procedures describe how to cancel QAnywhere messages.

**Note**

You cannot cancel a message using the QAnywhere SQL API.

### ◆ To cancel a message (.NET)

1. Get the ID of the message to cancel.

```
// msg is a QAMessage instance that has not been
// transmitted.
string msgID = msg.getMessageID();
```

2. Call `CancelMessage` with the ID of the message to cancel.

```
mgr.CancelMessage(msgID);
```

☞ For more information, see [“CancelMessage method” on page 283](#).

### ◆ To cancel a message (C++)

1. Get the ID of the message to cancel.

```
// msg is a QAMessage instance that has not been
// transmitted.
qa_string msgID = msg->getMessageID();
```

2. Call `cancelMessage` with the ID of the message to cancel.

```
bool result = mgr->cancelMessage(msgID);
```

☞ For more information, see [“cancelMessage function” on page 438](#).

### ◆ To cancel a message (Java)

1. Get the ID of the message to cancel.

```
// msg is a QAMessage instance that has not been
// transmitted.
String msgID = msg.getMessageID();
```

2. Call `cancelMessage` with the ID of the message to cancel.

```
boolean result = mgr.cancelMessage(msgID);
```

For more information, see [“cancelMessage method” on page 544](#).

## Receiving QAnywhere messages

The following topics describe how to receive QAnywhere messages.

### Receiving messages synchronously

To receive messages synchronously, your application explicitly polls the queue for messages. It may poll the queue periodically, or when a user initiates a particular action such as clicking a Refresh button.

#### ◆ To receive messages synchronously (.NET)

1. Declare message objects to hold the incoming messages.

```
QAMessage msg;
QATextMessage text_msg;
```

2. Poll the message queue, collecting messages:

```
if(mgr.start()) {
    for(;;) {
        msg = mgr.GetMessageNoWait("queue-name");
        if( msg == null ) {
            break;
        }
        addMessage( msg );
    }
    mgr.stop();
}
```

☞ For more information, see [“GetMessageNoWait method” on page 292](#).

#### ◆ To receive messages synchronously (C++)

1. Declare message objects to hold the incoming messages.

```
QAMessage * msg;
QATextMessage * text_msg;
```

2. Poll the message queue, collecting messages:

```
if( mgr->start() ) {
    for( ;; ) {
        msg = mgr->getMessageNoWait( "queue-name" );
        if( msg == NULL ) {
            break;
        }
        addMessage(msg);
    }
    mgr->stop();
}
```

☞ For more information, see [“getMessageNoWait method” on page 552](#).

### ◆ To receive messages synchronously (Java)

1. Declare message objects to hold the incoming messages.

```
QAMessage msg;  
QATextMessage text_message;
```

2. Poll the message queue, collecting messages:

```
if(mgr.start()) {  
    for ( ;; ) {  
        msg = mgr.getMessageNoWait("queue-name");  
        if ( msg == null ) {  
            break;  
        }  
        addMessage(msg);  
    }  
    mgr.stop();  
}
```

☞ For more information, see [“getMessageNoWait method” on page 552](#).

### ◆ To receive messages synchronously (SQL)

1. Declare an object to hold the message ID.

```
begin  
    declare @msgid varchar(128);
```

2. Poll the message queue, collecting messages.

```
    loop  
        set @msgid = ml_qa_getmessagingnowait( 'myaddress' );  
        if @msgid is null then leave end if;  
        message 'a message with content ' || ml_qa_gettextcontent( @msgid )  
    || ' has been received';  
    end loop;  
    commit;  
end
```

For more information, see:

- ◆ [“ml\\_qa\\_getmessagingnowait” on page 668](#)
- ◆ [“ml\\_qa\\_getmessagingtimeout” on page 669](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

## Receiving messages asynchronously

To receive messages asynchronously using the .NET, C++, and Java APIs, you can write and register a message listener function that is called by QAnywhere when a message appears in the queue. The message listener takes the incoming message as a parameter. The task you perform in your message listener depends on your application. For example, in the TestMessage sample application the message listener adds the message to the list of messages in the main TestMessage window.

### ◆ To receive messages asynchronously (.NET)

1. Implement a message handler method.

```
private void onMessage(QAMessage msg) {
    // Process message.
}
```

2. Register the message handler.

To register a message handler, create a `QAManager.MessageListener` object that has the message handler function as its argument. Then use the `QAManager.SetMessageListener` function to register the `MessageListener` with a specific queue. In the following example, *queue-name* is a string and *listener* is the name of the queue the `QAManager` object listens to.

```
MessageListener listener;
listener = new MessageListener( onMessage );
mgr.SetMessageListener( "queue-name", listener );
```

☞ For more information about `MessageListener`, see [“MessageListener delegate” on page 245](#).

☞ For more information about `SetMessageListener`, see [“SetMessageListener method” on page 303](#).

### ◆ To receive messages asynchronously (C++)

1. Create a class that implements the `QAMessageListener` interface.

```
class MyClass: public QAMessageListener {
public:
    void onMessage( QAMessage * Msg);
};
```

☞ For more information, see [“QAMessageListener class” on page 487](#).

2. Implement the `onMessage` method.

The `QAMessageListener` interface contains one method, `onMessage`. Each time a message arrives in the queue, the QAnywhere library calls this method, passing the new message as the single argument.

```
void MyClass::onMessage(QAMessage * msg) {
    // Process message.
}
```

3. Register the message listener.

```
my_listener = new MyClass();
mgr->setMessageListener( "queue-name", my_listener );
```

☞ For more information, see [“setMessageListener function” on page 457](#).

### ◆ To receive a message asynchronously (Java)

1. Implement a message handler method and an exception handler method.

```
class MyClass implements QAMessageListener {
    public void onMessage(QAMessage message) {
        // Process the message.
    }
    public void onException(
        QAEException exception, QAMessage message) {
        // Handle the exception.
    }
}
```

2. Register the message handler.

```
MyClass listener = new MyClass();
mgr.setMessageListener("queue-name", listener);
```

For more information, see:

- ◆ [“Interface QAMessageListener” on page 588](#)
- ◆ [“setLongStoreProperty method” on page 561](#)

### ◆ To receive messages asynchronously (SQL)

- Create a stored procedure with the name `ml_qa_listener_queue`, where *queue* is the name of a message queue.

This procedure is called whenever a message is queued on the given queue.

☞ See [“ml\\_qa\\_listener\\_queue” on page 670](#).

## Development tip for .NET, C++ and Java

It is safer to use QAManagers in mode `EXPLICIT_ACKNOWLEDGEMENT` to guard against the possibility of an application error occurring part way through the processing of received messages and the message being acknowledged anyway.

If the QAManager is opened in mode `EXPLICIT_ACKNOWLEDGEMENT`, the message can be acknowledged in the `onMessage` method only after it has been successfully processed. That way if there was an error processing the message, the message will be received again because it was not acknowledged.

If the QAManager is opened in mode `IMPLICIT_ACKNOWLEDGEMENT`, the message passed to `onMessage` is acknowledged implicitly when `onMessage` returns. If the user application encounters an error while processing the message, the message is acknowledged and never received again.

## Receiving messages using a selector

You can use **message selectors** to select messages for receiving. A message selector is a SQL-like expression that specifies a condition to select a subset of messages to consider for receive operations.

The syntax and semantics of message selectors are exactly the same as the condition part of transmission rules.

☞ See [“Condition syntax” on page 228](#).

**Example**

The following C# example gets the next message from receiveQueue that has a message property called intprop with value 1.

```
msg = receiver.GetMessageBySelectorNoWait(  
    receiveQueue, "intprop=1" );
```

The following C++ example gets the next message from receiveQueue that has a message property called intprop with value 1.

```
msg = receiver->getMessageBySelectorNoWait(  
    receiveQueue, "intprop=1" );
```

The following Java example gets the next message from receiveQueue that has a message property called intprop with value 1.

```
msg = receiver.getMessageBySelectorNoWait(  
    receiveQueue, "intprop=1");
```

- ◆ [C++: “getMessageBySelector function” on page 446 and “getMessageBySelectorNoWait function” on page 447](#)
- ◆ [Java: “getMessageBySelector method” on page 550 and “getMessageBySelectorNoWait method” on page 551](#)
- ◆ [SQL: the SQL API does not support receiving messages using a selector](#)

## Reading very large messages

Sometimes messages are so large that they exceed the limit set with the QAManager property `MAX_IN_MEMORY_MESSAGE_SIZE` or its defaults of 1MB on Windows and 64KB on Windows CE. In this case, the message object cannot contain the full content of the message in memory, so methods that rely on the full content of the message being loaded into memory, such as `readInt()` and `readString()`, cannot be used. However, you can read very large messages directly from the message store in pieces. To do this, use `QATextMessage.readText()` or `QABinaryMessage.readBinary()` in a loop.

For more information, see:

- ◆ .NET: [“ReadBinary method” on page 258](#) and [“ReadText method” on page 336](#)
- ◆ C++: [“readBinary function” on page 406](#) and [“readText function” on page 490](#)
- ◆ Java: [“readBinary method” on page 517](#) and [“readText method” on page 591](#)
- ◆ SQL: the SQL API does not support receiving very large messages

When you do this, you cannot use a QAManager that was opened with `IMPLICIT_ACKNOWLEDGEMENT`. You must use a QAManager that was opened with `EXPLICIT_ACKNOWLEDGEMENT` and you must complete all calls to `readText()` or `readBinary()` before acknowledging the message.

☞ For more information, see [“Acknowledgement modes” on page 59](#).

## Browsing QAnywhere messages

You can browse messages in incoming and outgoing queues. Browse operations do not affect the status of messages.

☞ For more information about message status, see `ias_Status` in “[Pre-defined message properties](#)” on page 209.

The following topics describe how to browse QAnywhere messages.

### Browse all messages

You can browse the messages in all queues by calling the appropriate `browseMessages()` method.

#### Example

The following .NET example uses the `QAManager.BrowseMessages()` method to browse all queues:

```
QAMessage msg;
IEnumerator msgs = mgr.BrowseMessages();
while( msgs.MoveNext() ) {
    msg = (QAMessage)msgs.Current;
    // Process message.
}
```

The following C++ example uses the `QAManager browseMessages` function to browse all queues:

```
QAMessage *msg;
qa_browse_handle bh = mgr->browseMessages();
for (;;) {
    msg = mgr->browseNextMessage( bh );
    if( msg == qa_null ) {
        break;
    }
    // Process message.
    mgr->browseClose( bh );
}
```

The following Java example uses the `QAManager.browseMessages` method to browse all queues:

```
QAMessage msg;
java.util.Enumeration msgs = mgr.browseMessages();
while( msgs.hasMoreElements() ) {
    msg = (QAMessage)msgs.nextElement();
    // Process message.
}
```

#### See also

- ◆ [.NET: “BrowseMessages method” on page 280](#)
- ◆ [C++: “browseMessages function” on page 434](#)
- ◆ [Java: “browseMessages method” on page 542](#)
- ◆ SQL: the SQL API does not support browsing messages

## Browsing messages in a queue

You can browse the messages in a given queue by supplying the queue name to the appropriate `browseMessagesByQueue()` method.

### Example

The following .NET example uses the `QAManager.BrowseMessagesByQueue` method to browse a queue:

```
QAMessage msg;
IEnumerator msgs = mgr.BrowseMessagesByQueue( "q1" );
while( msgs.MoveNext() ) {
    msg = (QAMessage)msgs.Current;
    // Process message.
}
```

The following C++ example uses the `QAManager.browseMessagesByQueue` function to browse a queue:

```
QAMessage *msg;
qa_browse_handle bh = mgr->browseMessagesByQueue( _T("q1" ) );
for (;;) {
    msg = mgr->browseNextMessage( bh );
    if( msg == qa_null ) {
        break;
    }
    // Process message.
}
mgr->browseClose( bh );
```

The following Java example uses the `QAManager.browseMessagesByQueue` method to browse a queue:

```
QAMessage msg;
java.util.Enumeration msgs = mgr.browseMessagesByQueue( "q1" );
while( msgs.hasMoreElements() ) {
    msg = (QAMessage)msgs.nextElement();
    // Process message.
}
```

### See also

- ◆ C++: [“browseMessagesByQueue function” on page 436](#)
- ◆ Java: [“browseMessagesByQueue method” on page 543](#)
- ◆ SQL: the SQL API does not support browsing messages

## Browsing a message by ID

You can browse a particular message by specifying its ID to a `browseMessagesbyID()` method.

### Example

The following .NET example uses the `QAManager.BrowseMessageByID` method to browse a message:

```
QAMessage msg;
IEnumerator msgs = mgr.BrowseMessagesByID( "ID:123" );
if( msgs.MoveNext() ) {
    msg = (QAMessage)msgs.Current;
    // Process message.
}
```

The following C++ example uses the QAManager browseMessageByID function to browse a message :

```
QAMessage *msg;
qa_browse_handle bh = mgr->browseMessagesByID( _T( "ID:123" ) );
msg = mgr->browseNextMessage( bh );
if( msg != qa_null ) {
    // Process message.
}
mgr->browseClose( bh );
```

The following Java example uses the QAManager.browseMessageByID method to browse a message:

```
QAMessage msg;
java.util.Enumeration msgs = mgr.browseMessagesByID( "ID:123" );
if( msgs.hasMoreElements() ) {
    msg = (QAMessage)msgs.nextElement();
    // Process message.
}
```

### See also

- ◆ .NET: [“BrowseMessagesByID method” on page 281](#)
- ◆ C++: [“browseMessagesByID function” on page 435](#)
- ◆ Java: [“browseMessagesByID method” on page 542](#)
- ◆ SQL: the SQL API does not support browsing messages

## Browsing messages using a selector

You can use **message selectors** to select messages for browsing. A message selector is a SQL-like expression that specifies a condition to select a subset of messages to consider for browse operations.

The syntax and semantics of message selectors are exactly the same as the condition part of transmission rules.

☞ See [“Condition syntax” on page 228](#).

### Example

The following .NET example browses all messages in the message store that have a property called intprop with value 1.

```
QAMessage msg;
IEnumerator msgs = mgr.BrowseMessagesBySelector( "intprop = 1" );
while( msgs.MoveNext() ) {
    msg = (QAMessage)msgs.Current;
    // Process message.
}
```

The following C++ example browses all messages in the message store that have a property called intprop with value 1.

```
QAMessage *msg;
qa_browse_handle bh = mgr->browseMessagesBySelector( _T("intprop = 1") );
for ( ;; ) {
    msg = mgr->browseNextMessage( bh );
    if( msg == qa_null ) {
        break;
    }
}
```

```
    }  
    // Process message.  
  }  
  mgr->browseClose( bh );
```

The following Java example browses all messages in the message store that have a property called `intprop` with value 1.

```
QAMessage msg;  
java.util.Enumeration msgs = mgr.browseMessagesBySelector( "intprop = 1" );  
while( msgs.hasMoreElements() ) {  
    msg = (QAMessage)msgs.nextElement();  
    // Process message.  
}
```

- ◆ Java: [“browseMessagesBySelector method” on page 544](#)
- ◆ SQL: the SQL API does not support browsing messages

## Handling QAnywhere exceptions

The QAnywhere C++, Java, and .NET APIs include special objects and properties for exception handling.

### .NET exceptions

The `QAEException` class encapsulates QAnywhere client application exceptions. After you catch a QAnywhere exception, you can use the `QAEException` `ErrorCode` and `Message` properties to determine the error code and error message.

Note that if a `QAEException` is thrown inside a message listener delegate and it is not caught in the message listener, then it will be logged to the `QAManager` log file. Since uncaught `QAEExceptions` are only logged, it is recommended that all exceptions be handled within message listener delegates so that they can be dealt with appropriately.

☞ For more information about the log file, see [“QAnywhere manager configuration properties” on page 62](#).

When a `QAEException` is thrown the current transaction is rolled back. When this happens in a message listener with a `QATransactionalManager`, the message that was being processed when the `QAEException` was thrown is put back in the receive queue and so that it will be re-received. You can use the message store property `ias_MaxDeliveryAttempts` to prevent an infinite loop.

When the property `ias_MaxDeliveryAttempts` is set to a positive integer  $n$  by a QAnywhere application, as in `mgr.SetIntStoreProperty( "ias_MaxDeliveryAttempts", 5 )`, the QAnywhere client will attempt to receive an unacknowledged message up to  $n$  times before setting the status of the message to unreceivable. If the property `ias_MaxDeliveryAttempts` is not set or is negative, the QAnywhere client will attempt to receive messages an unlimited number of times.

For more information, see:

- ◆ [“QAEException class” on page 269](#)
- ◆ [“ErrorCode property” on page 271](#)

The following table lists error code values for the `LastError` property:

LastError value	Description
0	No error.
1000	Initialization error.
1001	Termination error.
1002	Unable to access the client properties file.
1003	No destination.
1004	The function is not implemented.
1005	You cannot write to a message as it is in read-only mode.

LastError value	Description
1006	Error storing a message in the client message store.
1007	Error retrieving a message from the client message store.
1008	Error initializing the background thread.
1009	Error opening a connection to the message store.
1010	There is an invalid property in the client properties file.
1011	Error opening the log file.
1012	Unexpected end of message reached.
1013	The message store is too large relative to the free disk space on the device.
1014	The message store has not been initialized for messaging.
1015	Error getting queue depth.
1016	Cannot use QAManagerBase.getQueueDepth when the message store ID has not been set.
1017	Cannot use QAManagerBase.getQueueDepth on a given destination when filter is ALL.
1018	Error cancelling message.
1019	Error cancelling message. Cannot cancel a message that has already been sent.
1020	Error acknowledging the message.
1021	The QAManager is not open.
1022	The QAManager is already open.
1023	The given selector has a syntax error.
1024	The timestamp is outside of the acceptable range.

### C++ exceptions

For C++, the QAEError class encapsulates QAnywhere client application exceptions. You can use the QAManagerBase::getLastError() method or QAManagerFactory::getLastError() method to determine the error code associated with the last executed method. You can use the corresponding getLastErrorMessage() method to obtain the error text.

☞ For a list of error codes and more information, see [“QAEError class” on page 418](#).

For more information about getLastError and getLastErrorMessage, see:

- ◆ QAManagerBase [“getLastError function” on page 444](#) and [“getLastErrorMsg function” on page 444](#).

- ◆ QAManagerFactory [“getLastError function” on page 464](#) and [“getLastErrorMsg function” on page 464](#).

### Java exceptions

For Java, the QAException class encapsulates QAnywhere client application exceptions. You can catch the exception to determine the error code and error text associated with the last executed method.

- ☞ For a list of error codes and more information, see [“Class QAException” on page 530](#).

## Shutting down QAnywhere

After you have completed sending and receiving messages, you can shut down the QAnywhere messaging system by completing one of the following procedures.

### ◆ To shut down QAnywhere (.NET)

- Stop and close the QAnywhere manager.

```
mgr.Stop();  
mgr.Close();
```

### ◆ To shut down QAnywhere (C++)

1. Close the QAnywhere manager.

```
mgr->stop();  
mgr->close();
```

2. Terminate the factory.

```
QAnywhereFactory_term();
```

This step shuts down the messaging part of your application.

### ◆ To shut down QAnywhere (Java)

- Stop and close the QAnywhere manager.

```
mgr.stop();  
mgr.close();
```

### See also

# Server management requests

## Contents

About server management requests .....	92
Administering the server message store with server management requests .....	101
Administering connectors .....	104
Setting server properties with a server management request .....	114
Specifying transmission rules with a server management request .....	116
Creating destination aliases using server management requests .....	117
Monitoring QAnywhere .....	120
Monitoring QAnywhere clients .....	124
Monitoring properties .....	125

### About this chapter

This chapter describes how to use server management requests to perform administrative tasks and to monitor QAnywhere messaging.

## About server management requests

A QAnywhere client application can send special messages to the server called **server management requests**. These messages contain content that is formatted as XML and are addressed to the QAnywhere system queue. They require a special authentication string. Server management requests can perform a variety of functions, such as:

- ◆ Starting and stopping connectors and web services.

See [“Opening connectors” on page 106](#) and [“Closing connectors” on page 106](#).

- ◆ Monitoring connector status.

See [“Monitoring connectors” on page 107](#).

- ◆ Setting and refreshing client transmission rules.

See [“Specifying transmission rules with a server management request” on page 116](#).

- ◆ Monitoring message status.

See [“Monitoring QAnywhere” on page 120](#).

- ◆ Setting, updating, deleting, and querying client message store properties on the server.

See [“Setting server properties with a server management request” on page 114](#).

- ◆ Cancelling messages.

See [“Cancelling messages” on page 101](#).

- ◆ Querying for active clients, message store properties, and messages.

### Addressing server management requests

By default, server management requests must be addressed to **ianywhere.server\system**. To change the client ID portion of this address, set the `ianywhere.qa.server.id` property and restart the server. For example, if the `ianywhere.qa.server.id` property is set to `myServer`, server management requests are addressed to `myServer\system`.

☞ For more information about setting the `ianywhere.qa.server.id` property, see [“Server properties” on page 222](#).

☞ For more information about addressing QAnywhere messages, see [“Sending QAnywhere messages” on page 66](#).

☞ For more information about the system queue, see [“System queue” on page 51](#).

## Authenticating server management requests

The message string property `ias_ServerPassword` specifies the server password. The server password is set using the `ianywhere.qa.server.password.e` property. If this property is not set, the password is `QAnywhere`.

The server password is transmitted as text. Use an encrypted communication stream to send server management requests that require a server password.

For more information about the `ianywhere.qa.server.password.e` property, see [“Server properties” on page 222](#).

## Examples

The following is a sample message details request. It generates a single report that displays the message ID, status, and target address of all messages with priority 9 currently on the server.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <MessageDetailsRequest>
    <request>
      <requestId>testRequest</requestId>
      <condition>
        <priority>9</priority>
      </condition>
      <status/>
      <address/>
    </request>
  </MessageDetailsRequest>
</actions>
```

The following example is in C#. It sets a server-side transmission rule for a client such that messages from the server are only transmitted to the client called `someClient` if the priority is greater than 4.

```
QAManager mgr = ...; // Initialize the QAManager
QAMessage msg = mgr.CreateTextMessage();
msg.SetStringProperty( "ias_ServerPassword", "QAnywhere" );

// Indenting and newlines are just for readability
msg.Text = "<?xml version="1.0" encoding="UTF-8"?>\n"
+ "<actions>\n"
+ "  <SetProperty>\n"
+ "    <prop>\n"
+ "      <client>someClient</client>\n"
+ "      <name>ianywhere.qa.server.rules</name>\n"
+ "      <value>ias_Priority > 4</value>\n"
+ "    </prop>\n"
+ "  </SetProperty>\n"
+ "  <RestartRules>\n"
+ "    <client>someClient</client>\n"
+ "  </RestartRules>\n"
+ "</actions>\n";

mgr.PutMessage( @"ianywhere.server\system", msg );
```

## Writing server management requests

Server management requests contain content that is formatted as XML.

**Note**

You cannot use symbols such as > or < in the content of server management requests. Instead, use &gt; and &lt;.

Each server management request starts with an <actions> tag.

Each type of server management request includes its own XML tags. For example, to close a connector you use the <CloseConnector> tag.

**request tag**

In addition, most server management requests can include a <request> tag that describes the request. Within a <request> tag, you can use the following subtags:

<request> subtags	Description
<condition>	Groups conditions for including a message in the report. Only used in the <request> tag, which is a subtag of <MessageDetailsRequest> and <CancelMessageRequest>.
<onEvent>	Specifies the events upon which the server should generate reports. Only used with <ClientStatusRequest>. You can include one or more <onEvent> tags, with one event type per tag. If these tags are omitted, the Client Status Request produces a one-time request. Otherwise, the Client Status Request registers event listeners for the specified events.
<persistent>	Specifies that the results of the request should be made persistent in the server database (so that the report is sent even if the server is restarted). Only used with schedules.
<report>	Specifies that a report should be sent each time the request is activated. Only used in the <request> tag, which is a subtag of <CancelMessageRequest>.
<requestId>	Specifies a unique identifier for the request that is included in each report generated as a result of this request. Only used when a server management request generates a response or report. Using different values for this field allows more than one request to be active at the same time. Using the same request ID allows the client to override or delete active requests.
<replyAddr>	Specifies the return address for each report generated as a result of this request. If this tag is omitted, the default return address of reports is the reply address of the originating message. Only used when a server management request generates a response or report.
<schedule>	Specifies that the report should be generated on a schedule. Only used when a server management request generates a response or report. See <a href="#">“Scheduling server management requests” on page 98</a> .

**Condition tag**

Use the following condition subtags to filter the messages to include in the MessageDetailsRequest. You can specify as many of these tags as you want in the <condition> tag. If you use more than one of the same

tag, then the values given are logically "OR"ed together, whereas if you use two different tags, the values are logically "AND"ed together.

<b>&lt;condition&gt; subtags</b>	<b>Description</b>
<address>	Selects the messages that are addressed to the specified address.
<customRule>	Selects messages based on rules. See <a href="#">“Custom message requests” on page 95</a> .
<kind>	Filters either binary or text messages.  For example, <b>&lt;kind&gt;text&lt;/kind&gt;</b> filters text messages, and <b>&lt;kind&gt;binary&lt;/kind&gt;</b> filters binary messages.
<messageId>	Selects the message with a particular message ID.
<originator>	Selects messages that originated from the specified client.
<priority>	Selects the messages that currently have the priority specified.
<property>	Selects messages that have the specified message property. To check a property name and value, use the syntax <b>&lt;property&gt;property-name=property-value&lt;/property&gt;</b> . To check the existence of a property, use the format <b>&lt;property&gt;property-name&lt;/property&gt;</b> .
<status>	Selects messages that currently have the status specified.

## Custom message requests

To construct more complex condition statements, use the <customRule> tag as a subtag to the <condition> tag (and other tags). This tag takes as its data a server rule similar to those used for server transmission rules. You can construct these queries in the same manner as the condition part of a transmission rule.

☞ See [“Condition syntax” on page 228](#).

### Example

The following condition selects messages following the search criteria: ( priority=4 ) AND ( originator LIKE '%sender%' AND status >= 20 )

```
<condition>
  <priority>4</priority>
  <customRule>ias_Originator LIKE '%sender%' AND ias_Status >=
ias_FinalState</customRule>
</condition>
```

## Server management request DTD

Following is the complete definition of the server management request XML document type. This DTD is provided as a summary of the server management tags that are described in this chapter.

```
<!-- Set of requests -->
<!ELEMENT actions ((CloseConnector|OpenConnector|RestartRules|SetProperty
|ClientStatusRequest|MessageDetailsRequest|CancelMessageRequest
|GetClientList)+)>
<!-- Request for list of all clients -->

<!ELEMENT statusSubcode (#PCDATA)>
<!ELEMENT vendorStatusCode (#PCDATA)>
<!ELEMENT vendorStatusDescription (#PCDATA)>
```

## Scheduling server management requests

You can optionally set up server management requests to run on a schedule. Use the following <schedule> subtags to define the schedule on which the request runs.

<schedule> subtags	Description
<starttime>	Defines the time of day at which the server begins generating reports. For example:  <pre>&lt;starttime&gt;09:00:00&lt;/starttime&gt;</pre>
<between>	Contains two subtags, starttime and endtime, which define an interval during which the server generates reports. May not be used in the same schedule as starttime. For example:  <pre>&lt;between&gt;   &lt;starttime&gt;Mon Jan 16 09:00:00 EST 2006&lt;/starttime&gt;   &lt;endtime&gt;Mon Jan 17 09:00:00 EST 2006&lt;/endtime&gt; &lt;/between&gt;</pre>
<everyhour>	Defines the interval between subsequent reports in hours. May not be used in the same schedule as everyminute or everysecond. For example, the following request generates a report every two hours starting on January 16 at 9 AM:  <pre>&lt;schedule&gt;   &lt;starttime&gt;09:00:00&lt;/starttime&gt;   &lt;everyhour&gt;2&lt;/everyhour&gt; &lt;/schedule&gt;</pre>
<everyminute>	Defines the interval between subsequent reports in minutes. May not be used in the same schedule as everyhour or everysecond.  <pre>&lt;schedule&gt;   &lt;everyminute&gt;10&lt;/everyminute&gt; &lt;/schedule&gt;</pre>
<everysecond>	Defines the interval between subsequent reports in seconds. May not be used in the same schedule as everyhour or everyminute.  <pre>&lt;schedule&gt;   &lt;everysecond&gt;45&lt;/everysecond&gt; &lt;/schedule&gt;</pre>
<ondayofweek>	Each tag contains one day of the week in which the schedule is active. For example, the following schedule runs on Mondays and Tuesdays:  <pre>&lt;schedule&gt;   &lt;ondayofweek&gt;Monday&lt;/ondayofweek&gt;   &lt;ondayofweek&gt;Tuesday&lt;/ondayofweek&gt; &lt;/schedule&gt;</pre>

<schedule> subtags	Description
<ondayofmonth>	Each tag contains one day of the month on which the schedule is active. For example, the following schedule runs on the fifteenth of the month: <pre data-bbox="555 343 1033 413" style="margin-left: 20px;">             &lt;schedule&gt;               &lt;ondayofmonth&gt;15&lt;/ondayofmonth&gt;             &lt;/schedule&gt;           </pre>
<startdate>	The date on which the schedule becomes active. For example: <pre data-bbox="555 494 1105 517" style="margin-left: 20px;">             &lt;startdate&gt;Mon Jan 16 2006&lt;/startdate&gt;           </pre>

To modify a schedule, register a new server management request with the same requestId. To delete a schedule, register a server management request with the same requestId, but include the schedule tag <schedule>none</schedule>.

### Notes

- ◆ Each tag, except for the <ondayofweek> and <ondayofmonth> tags, can only be used once in a schedule.
- ◆ The <between> tag and the individual <starttime> tag may not both be used in the same schedule.
- ◆ Only one of <everysecond>, <everyminute>, and <everyhour> may be used in the same schedule.

### Example

The following example creates a persistent schedule that will report on all the messages on the server, including the ID and status of each message. It will also overwrite any previous persistent requests assigned to the request ID dailyMessageStatus.

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <MessageDetailsRequest>
    <request>
      <replyAddr>myclient\messageStatusQueue</replyAddr>
      <requestId>dailyMessageStatus</requestId>
      <schedule>
        <everyhour>24</everyhour>
      </schedule>
      <persistent/>
      <messageId/>
      <status/>
    </request>
  </MessageDetailsRequest>
</actions>

```

Following is an example of what the report might look like. It is sent to the address myclient\messageStatusQueue. It indicates that there are two messages on the server, one with status 60 (received) and one with status 1 (pending).

```

<?xml version="1.0" encoding="UTF-8"?>
<MessageDetailsReport>
  <requestId>dailyMessageStatus</requestId>
  <UTCDateTime>Mon Jan 16 15:03:04 EST 2007</UTCDateTime>
  <statusDescription>Scheduled report</statusDescription>
  <messageCount>2</messageCount>
  <message>
    <messageId>ID:26080b8927f83f9722357eab0a0628eb</messageId>

```

```
      <status>60</status>
    </message>
  <message>
    <messageId>ID: fe857fa8-a7d7-4266-985b-a1818a85d1a2</messageId>
    <status>1</status>
  </message>
</MessageDetailsReport>
```

# Administering the server message store with server management requests

You can use server management requests to administer the server message store.

☞ For an overview of how to use server management requests, including how to authenticate and schedule them, see [“About server management requests” on page 92](#).

## Refreshing client transmission rules

When a server-side client transmission rule is changed, the rules for the corresponding client must be refreshed. You can do this in a server management request by setting the property `ianywhere.qa.server.rules`.

A `RestartRules` tag contains a single client tag, which specifies the name of the client to refresh.

<code>&lt;RestartRules&gt;</code> subtags	Description
<code>&lt;client&gt;</code>	The name of the client for which to refresh transmission rules.

### Example

The server XML needs to specify the new transmission rule property and then restart rule processing using the `RestartRules` tag. For example, the following XML changes the server-side transmission rule for client `myclient` to `auto = ias_Priority > 4`. Note the proper encoding of `>` in the XML.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>myclient</client>
      <name>ianywhere.qa.server.rules</name>
      <value>auto = ias_Priority &gt; 4</value>
    </prop>
  </SetProperty>
  <RestartRules>
    <client>myclient</client>
  </RestartRules>
</actions>
```

## Cancelling messages

You can create a server management request to cancel messages in the server message store. You can create a one-time cancellation request or you can schedule your cancellation request to happen automatically. You can also optionally generate a report that details the messages that have been cancelled.

Messages can only be cancelled if they are on the server and in a non-final state when the request is activated.

<b>&lt;CancelMessageRequest&gt; subtags</b>	
<request>	Groups information about a particular request. Specifying more than one <request> tag is equivalent to sending multiple separate server management requests.
<b>&lt;Request&gt; subtags</b>	<b>Description</b>
<condition>	Groups conditions for including a message to be cancelled. See <a href="#">“Condition tag” on page 94.</a>
<persistent>	Specifies that the request should be made persistent in the server database (so that messages can be cancelled even if the server is restarted). Only used with schedules.
<requestId>	Specifies a unique identifier for the request that is included in each report generated as a result of this request. Using different values for this field allows more than one request to be active at the same time. Using the same request id allows the client to override or delete active requests.
<replyAddr>	The return address for each report generated as a result of this request. If this tag is omitted, the default return address of reports is the return address of the originating message.
<report>	Causes a report to be sent each time the request is activated. To cause a report to be sent each time the request is activated, put an empty <report> tag inside the <request> tag.
<schedule>	Specifies that the report should be generated on a schedule. See <a href="#">“Scheduling server management requests” on page 98.</a>

### Example

This request cancels messages on the server with the address `ianywhere.connector.myConnector\deadqueue`:

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <CancelMessageRequest>
    <request>
      <requestId>cancelRequest</client>
      <condition>
        <customRule>ias_Address='ianywhere.connector.myConnector
\deadqueue'</customRule>
      </condition>
    </request>
  </CancelMessageRequest>
</actions>
```

### Deleting messages

To specify a clean-up policy on the server, set the property `ianywhere.qa.server.deleteRules` for the special client `ianywhere.server.deleteRules` with the rule or rules governing which messages can be deleted from the server.

The following example changes the message clean-up policy to delete expired and cancelled messages:

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>ianywhere.server.deleteRules</client>
      <name>ianywhere.qa.server.deleteRules</name>
      <value>auto = ias_Status in ( ias_ExpiredStatus, ias_CancelledStatus )
and ias_TransmissionStatus = IAS_TRANSMITTED</value>
    </prop>
  </SetProperty>
  <RestartRules>
    <client>ianywhere.server.deleteRules</client>
  </RestartRules>
</actions>
```

## Administering connectors

You can use server management requests to create, configure, delete, start, stop, and monitor connectors.

☞ For an overview of how to use server management requests, including how to authenticate and schedule them, see [“About server management requests” on page 92](#).

### See also

- ◆ [“JMS Connectors” on page 127](#)
- ◆ [“Setting up web service connectors” on page 195](#)

## Creating and configuring connectors

To create connectors, use `<OpenConnector>`.

### Example

In the following example, the server management request first sets a number of relevant properties and associates them with the client `ianywhere.connector.jboss`, which is the client ID of the new connector. JMS-specific properties are set in such a way that a connector to a local JBOSS JMS server are indicated. The connector is then started using the `OpenConnector` tag. Note that if you have not started the MobiLink server with the relevant jar files of the JMS client, the connector will not be started.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>ianywhere.connector.nativeConnection</name>
      <value>ianywhere.message.connector.jms.NativeConnectionJMS</value>
    </prop>
    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>ianywhere.connector.address</name>
      <value>ianywhere.connector.jboss</value>
    </prop>
    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>xjms.jndi.factory</name>
      <value>org.jnp.interfaces.NamingContextFactory</value>
    </prop>
    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>xjms.jndi.url</name>
      <value>jnp://0.0.0.0:1099</value>
    </prop>
    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>xjms.topicFactory</name>
      <value>ConnectionFactory</value>
    </prop>
    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>xjms.queueFactory</name>
      <value>ConnectionFactory</value>
    </prop>
  </SetProperty>
  <OpenConnector>
    <client>ianywhere.connector.jboss</client>
    <name>ianywhere.connector.jboss</name>
    <value>ianywhere.connector.jboss</value>
  </OpenConnector>
</actions>
```

```

    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>xjms.receiveDestination</name>
      <value>qanywhere_receive</value>
    </prop>
    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>xjms.deadMessageDestination</name>
      <value>qanywhere_deadMessage</value>
    </prop>
  </SetProperty>
</OpenConnector>
  <client>ianywhere.connector.jboss</client>
</OpenConnector>
</actions>

```

## Modifying connectors

To modify connectors, close the connector, change properties with the `<SetProperty>` tag, and then open the connector.

### Example

In the following example, the logging level of the connector is changed to 4. The connector with the ID `ianywhere.connector.jboss` is closed; the connector property `logLevel` is changed to 4, and then the connector is re-opened with the new log level.

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <CloseConnector>
    <client>ianywhere.connector.jboss</client>
  </CloseConnector>
  <SetProperty>
    <prop>
      <client>ianywhere.connector.jboss</client>
      <name>ianywhere.connector.logLevel</name>
      <value>4</value>
    </prop>
  </SetProperty>
  <OpenConnector>
    <client>ianywhere.connector.jboss</client>
  </OpenConnector>
</actions>

```

## Deleting connectors

To delete connectors, use `<SetProperty>` with a client name but no other values.

### Example

In the following example, the connector with the ID `ianywhere.connector.jboss` is closed. All of its properties are deleted by the `<SetProperty>` tag, omitting the name and value tags.

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <CloseConnector>
    <client>ianywhere.connector.jboss</client>
  </CloseConnector>

```

```

    <SetProperty>
      <prop>
        <client>ianywhere.connector.jboss</client>
      </prop>
    </SetProperty>
  </actions>

```

## Opening connectors

To open connectors, use `<OpenConnector>`.

An `OpenConnector` tag contains a single `client` tag that specifies the name of the connector to open.

<code>&lt;OpenConnector&gt;</code> subtag	Description
<code>&lt;client&gt;</code>	The name of the connector to open.

### See also

- ◆ [“JMS Connectors” on page 127](#)
- ◆ [“Setting up web service connectors” on page 195](#)

### Example

The following example opens the `simpleGroup` connector.

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <OpenConnector>
    <client>simpleGroup</client>
  </OpenConnector>
</actions>

```

## Closing connectors

To close connectors, use `<CloseConnector>`. A `CloseConnector` tag contains a single `client` tag that specifies the name of the connector to close.

<code>&lt;CloseConnector&gt;</code> subtags	Description
<code>&lt;client&gt;</code>	The name of the connector to close.

### See also

- ◆ [“JMS Connectors” on page 127](#)
- ◆ [“Setting up web service connectors” on page 195](#)

### Example

The following example closes the `simpleGroup` connector.

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <CloseConnector>

```

```

    <client>simpleGroup</client>
  </CloseConnector>
</actions>

```

## Monitoring connectors

To obtain information about connectors, write a special kind of server management request called a client status request. It contains a `<ClientStatusRequest>` tag that uses one or more `<request>` tags containing the information necessary to register the request.

Your client status request can obtain reports about connectors in several ways:

- ◆ Make a one-time request.
- ◆ Register a State Change Listener to have a report sent whenever the connector's state changes.
- ◆ Register an Error Listener to have a report sent whenever an error occurs on the connector.

In addition, you can schedule a report to be sent at certain times or intervals.

### ClientStatusRequest tag

To get information about connectors, use `<ClientStatusRequest>`.

A client status request is composed of one or more `<request>` tags containing all the necessary information to register the request.

<b>&lt;ClientStatusRequest&gt; subtag</b>	
<code>&lt;request&gt;</code>	Groups information in requests.

### request tag for client status requests

In the `<request>` tag, use an optional `<replyAddr>` tag to specify the return address for each report generated as a result of this request. If this tag is omitted, the default return address of reports is the reply address of the originating message.

Use an optional `<requestId>` to add a label for the request that is included in each report. When you register multiple requests, or when you delete or modify requests, the ID makes it possible to distinguish which reports were generated from a particular request.

To specify a list of connectors for the request, include one or more `<client>` tags, each with one connector address. In the case of a one-time request, all of the connectors are included in the report. In the case of an event listener request, the server listens to each of these connectors.

To specify that event details should be made persistent during any server downtime, specify the `<persistent>` tag. This tag does not require any data and can be of the form `<persistent/>` or `<persistent></persistent>`.

You can optionally specify a list of events by including one or more `<onEvent>` tags with one event type per tag. If these tags are omitted, the client status request produces a one-time request. Otherwise, the client status request registers event listeners for the specified events.

<b>&lt;request&gt; subtags for client status requests</b>	<b>Description</b>
<client>	You can include one or more <client> tags, with one connector address per tag. In the case of a one-time request, all of the connectors listed are included in the report. In the case of an event listener request, the server will begin to listen to each of these connectors.
<onEvent>	Specifies the events upon which the server should generate reports. You can include one or more <onEvent> tags, with one event type per tag. If these tags are omitted, the Client Status Request will produce a one-time request. Otherwise, the Client Status Request will be used to register event listeners for the specified events.
<persistent>	Specifies that the details information in this Client Status Request should be made persistent in the server database.
<replyAddr>	Specifies the return address for each report generated as a result of this request. If this tag is omitted, the default return address of reports is the reply address of the originating message.
<requestId>	A label for the report. This value is used as a label for the request and is included in each report generated as a result of this request. This makes it possible to distinguish which reports were generated from a particular request when multiple requests have been registered and to delete or modify outstanding requests.
<schedule>	See <a href="#">“Scheduling server management requests” on page 98.</a>

### condition tag

To filter the request, use <condition> subtags. You can use as many of the following subtags as you want in a <condition> tag. If you use more than one of the same tag, the values are logically "OR"ed together, whereas if you use two different tags, the values are logically "AND"ed together.

<b>&lt;condition&gt; subtags</b>	<b>Description</b>
<messageId>	Selects the message with a particular message ID.
<status>	Selects messages that currently have the status specified.
<priority>	Selects the messages that currently have the priority specified.
<address>	Selects the messages that are addressed to the specified address.
<originator>	Selects messages that originated from the specified client.

<condition> subtags	Description
<kind>	Filters either binary or text messages. For example, <b>&lt;kind&gt;text&lt;/kind&gt;</b> filters text messages, and <b>&lt;kind&gt;binary&lt;/kind&gt;</b> filters binary messages.
<property>	Selects messages that have the specified message property. To check a property name and value, use the syntax <b>&lt;property&gt;property-name=property-value&lt;/property&gt;</b> . To check the existence of a property, use the format <b>&lt;property&gt;property-name&lt;/property&gt;</b> .
<customRule>	Selects messages based on rules. See <a href="#">“Custom message requests” on page 95</a> .

### One-time client status requests

You create a one-time request by omitting <onEvent> tags from the client status request. In this case, a single report is generated that contains the current status information for each connector specified in the client status request.

The following XML message omits the <onEvent> tag and so is an example of a one-time request. It generates a single report containing the current status information for each connector specified in the <ClientStatusRequest> tag.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <ClientStatusRequest>
    <request>
      <replyAddr>ianywhere.connector.beajms\q11</replyAddr>
      <requestId>myOneTimeRequest</requestId>
      <client>ianywhere.server</client>
      <client>ianywhere.connector.beajms</client>
    </request>
  </ClientStatusRequest>
</actions>
```

### On-event client status requests

To specify events for which you want the QAnywhere Server to generate status reports, include one or more <onEvent> tags in your client status request. Unlike one-time requests, the server will not immediately respond to the request, but instead will begin listening for events to occur. Each time one of these events is triggered, a report is sent containing information about the connector that caused the event.

The following events are supported for on-event requests:

Event	When it occurs
open	A closed connector is opened.
close	A previously opened or paused connector is closed.
statusChange	The status of the connector is changed from one state to another. Possible states are open and close.

Event	When it occurs
error	An unexpected error is thrown by the connector.
fatalError	An unhandled fatal error is thrown by the connector.
none	This never occurs. This effectively removes all previous event watches from the connector.

In the following example, the connector with address `ianywhere.connector.beajms\q11` is sent a status report each time the server connector changes its status or generates an error.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <ClientStatusRequest>
    <request>
      <replyAddr>ianywhere.connector.beajms\q11</replyAddr>
      <requestId>myEventRequest</requestId>
      <client>ianywhere.server</client>
      <onEvent>statusChange</onEvent>
      <onEvent>error</onEvent>
    </request>
  </ClientStatusRequest>
</actions>
```

**Multiple simultaneous requests**

Each return address can have its own set of event listeners for any number of connectors, including the server connector. Adding an event listener to a connector will not disturb any other event listeners in the server (except possibly one that it is replacing).

**Request replacement**

If you add an event listener to a connector that already has an event listener registered to it by the same return address, it will replace the old listener with the new one. For example, if a `statusChange` listener for connector `abc` is registered to address `x/y` and you register an error listener for `abc` to address `x/y`, `abc` will no longer respond to `statusChange` events.

To register more than one event to the same address, you must create a single request with more than one `<onEvent>` tag.

**Removing a request**

If an event listener for a connector is registered to an address, you can remove the event listener by providing another client status request from the same address with the "none" event specified.

In the following example, all event listeners are removed for the server connector registered to the address `ianywhere.connector.beajms\q11`:

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <ClientStatusRequest>
    <request>
      <replyAddr>ianywhere.connector.beajms\q11</replyAddr>
      <client>ianywhere.server</client>
      <onEvent>none</onEvent>
    </request>
  </ClientStatusRequest>
</actions>
```

```

    </ClientStatusRequest>
  </actions>

```

### Persistent client status requests

To specify that the details of a request are saved into the global properties table on the message store (where they can be automatically reinstated after a server restart), include the `<persistent>` tag in a client status request. Persistence can be used with scheduled events and event listeners, but not one-time requests. The rules for adding and removing persistent requests are similar to those for regular requests, except that scheduled events and event listeners cannot be added separately. Instead, when adding a persistent request, the client must specify all event listeners and schedules for a particular connector/reply address pair in the same request.

The following example adds the event listener and schedule to `ianywhere.connector.myConnector` and makes them persistent. It also overwrites any previous persistent requests from this connector/reply address pair. A report will be sent every half hour, as well as any time a connector status change occurs.

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <ClientStatusRequest>
    <request>
      <replyAddr>ianywhere.connector.beajms\q11</replyAddr>
      <client>ianywhere.connector.myConnector</client>
      <onEvent>statusChange</onEvent>
      <schedule>
        <everyminute>30</everyminute>
      </schedule>
      <persistent/>
    </request>
  </ClientStatusRequest>
</actions>

```

### Client status reports

A client status report is generated by the server each time a report is requested by a connector or a registered event occurs. It is generated as a simple text message which does not contain any message properties.

Depending on what information is available at the time of the event, any of the following values may be included in each component report:

- ◆ client (always present)
- ◆ UTCDatetime (always present)
- ◆ vendorStatusDescription (always present)
- ◆ statusCode (always present)
- ◆ vendorStatusCode
- ◆ statusSubCode
- ◆ statusDescription

For example:

```

<?xml version="1.0" encoding="UTF-8"?>
<ClientStatusReport>
  <requestId>myRequest</requestId>
  <componentReport>
    <client>ianywhere.server</client>

```

```
<UTCdatetime>Tue May 31 13:53:02 EDT 2005</UTCdatetime>
<statusCode>Running</statusCode>
<vendorStatusDescription></vendorStatusDescription>
</componentReport>
<componentReport>
  <client>ianywhere.connector.beajms</client>
  <UTCdatetime>Tue May 31 13:53:02 EDT 2005</UTCdatetime>
  <statusCode>Not running</statusCode>
  <vendorStatusDescription></vendorStatusDescription>
</componentReport>
</ClientStatusReport>
```

### Monitoring connectors

Each return address can have its own set of event listeners for any number of connectors, including the server connector. Adding an event listener to a connector will not disturb any other event listeners in the server (except possibly one that it is replacing).

Adding an event listener to a connector that already has an event listener registered to it by the same return address will replace the old listener with the new one. For example, if a `statusChange` listener for connector `abc` is registered to address `x/y`, and then you register an `error` listener for `abc` to address `x/y`, `abc` will no longer respond to `statusChange` events. To register more than one event to the same address, you must use a single request by specifying more than one `<onEvent>` tag.

### Removing a request

If an event listener for a connector is registered to an address, you can remove the event listener by providing another client status request from the same address with the "none" event specified.

In the following example, all event listeners for the server connector registered to the address `ianywhere.connector.beajms\q11` are removed.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <ClientStatusRequest>
    <request>
      <replyAddr>ianywhere.connector.beajms\q11</replyAddr>
      <client>ianywhere.server</client>
      <onEvent>none</onEvent>
    </request>
  </ClientStatusRequest>
</actions>
```

### Event listener persistence

If a connector is closed, any event listeners it has registered to its address will persist in the server until the server is shut down. If the connector is reopened, the stored event listeners will become active again.

### Connector states

A connector can be in one of 2 states:

- ◆ **running** The connector is accepting and processing incoming and outgoing messages. This state is reflected in the connector property `ianywhere.connector.state=1`.

◆ **not running** The connector is not accepting or processing incoming or outgoing messages. When the connector state is changed to "running" the connector will be initialized from scratch. This state is reflected in the connector property `ianywhere.connector.state=2`.

☞ For information about how to change the connector state, see [“Modifying connectors” on page 105](#).

## Setting server properties with a server management request

A `<SetProperty>` tag contains one or more `<prop>` tags, each of which specifies a property to set. Each `prop` tag consists of a `<client>` tag, a `<name>` tag, and a `<value>` tag. To delete a property, omit the `<value>` tag.

<code>&lt;prop&gt;</code> subtags	Description
<code>&lt;client&gt;</code>	The name of the client for which to set a server property.
<code>&lt;name&gt;</code>	The name of the property to set.
<code>&lt;value&gt;</code>	The value of the property being set. If not included, the property will be deleted.

☞ For an overview of how to use server management requests, including how to authenticate and schedule them, see [“About server management requests” on page 92](#).

### Example

The following server management request sets the `ianywhere.qa.member.client3` property to `Y` for the destination alias called `simpleGroup`, which adds `client3` to `simpleGroup`.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.qa.member.client3</name>
      <value>Y</value>
    </prop>
  </SetProperty>
</actions>
```

The next example does the following:

- ◆ Creates or modifies the value of the `client1` property `myProp1` to `3`.
- ◆ Deletes the `client1` property `myProp2`.
- ◆ Modifies the value of the `client2` property `myProp3` to `"some value"`.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>client1</client>
      <name>myProp1</name>
      <value>3</value>
    </prop>
    <prop>
      <client>client1</client>
      <name>myProp2</name>
    </prop>
    <prop>
      <client>client2</client>
      <name>myProp3</name>
```

```
    <value>some value</value>
  </prop>
</SetProperty>
</actions>
```

## Specifying transmission rules with a server management request

With a server management request, you can specify default server transmission rules that apply to all users, or you can specify transmission rules for each client. You specify server transmission rules using the `ianywhere.qa.server.rules` property for a client.

To specify default transmission rules, set the `ianywhere.qa.server.rules` property for the client `ianywhere.server.defaultClient`.

 For an overview of how to use server management requests, including how to authenticate and schedule them, see [“About server management requests” on page 92](#).

### Example

The following example creates the default rule that only high priority messages (priority greater than 6) should be sent:

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>ianywhere.server.defaultClient</client>
      <name>ianywhere.qa.server.rules</name>
      <value>auto = ias_Priority &gt; 6</value>
    </prop>
  </SetProperty>
  <RestartRules>
    <client>ianywhere.server.defaultClient</client>
  </RestartRules>
</actions>
```

The following example creates a rule for client `sample_store_id` that only messages with a content size greater than 100 should be transmitted during business hours (8 a.m. and 6 p.m.):

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>ianywhere.server.defaultClient</client>
      <name>ianywhere.qa.server.rules</name>
      <value>auto = ias_ContentSize &lt; 100
        or ias_CurrentTime &lt; '8:00:00'
        or ias_CurrentTime &gt; '18:00:00'</value>
    </prop>
  </SetProperty>
  <RestartRules>
    <client>ianywhere.server.defaultClient</client>
  </RestartRules>
</actions>
```

## Creating destination aliases using server management requests

You can use server management requests to create and modify destination aliases.

☞ For more information about destination aliases, see [“Destination aliases” on page 50](#).

☞ For an overview of how to use server management requests, including how to authenticate and schedule them, see [“About server management requests” on page 92](#).

To create a destination alias, send a server management request in which the client name is the name of the destination alias and the following properties are specified. The group is identified by the group, address, and nativeConnection properties. Members of the group are specified with the member property.

```
<prop>
  <client>simpleGroup</client>
  <name>ianywhere.connector.nativeConnection</name>
  <value>ianywhere.message.connector.group.GroupConnector
</value>
</prop>
```

Property	Description
ianywhere.qa.group	Set this property to Y to indicate that you are configuring a destination alias. For example:  <pre>&lt;prop&gt;   &lt;client&gt;simpleGroup&lt;/client&gt;   &lt;name&gt;ianywhere.qa.group&lt;/name&gt;   &lt;value&gt;Y&lt;/value&gt; &lt;/prop&gt;</pre>
ianywhere.connector.address	Specify the client ID of the destination alias. For example:  <pre>&lt;prop&gt;   &lt;client&gt;simpleGroup&lt;/client&gt;   &lt;name&gt;ianywhere.connector.address&lt;/name&gt;   &lt;value&gt;simpleGroup&lt;/value&gt; &lt;/prop&gt;</pre>
ianywhere.connector.nativeConnection	Set to ianywhere.message.connector.group.GroupConnector. For example:  <pre>&lt;prop&gt;   &lt;client&gt;simpleGroup&lt;/client&gt;   &lt;name&gt;ianywhere.connector.nativeConnection&lt;/name&gt;    &lt;value&gt;ianywhere.message.connector.group.GroupConnector   &lt;/value&gt; &lt;/prop&gt;</pre>

Property	Description
ianywhere.qa.member. <i>client-name</i> \queue- <i>name</i>	<p>Specify Y to add a member or N to remove a member. You can also optionally specify a delivery condition. See <a href="#">“Condition syntax” on page 228</a>. For example, to add client1 to the destination alias simpleGroup, set the property as follows. The queue-name is optional. Repeat this property for every client you want to add:</p> <pre> &lt;prop&gt;   &lt;client&gt;simpleGroup&lt;/client&gt;   &lt;name&gt;ianywhere.qa.member.client1\queue1&lt;/name&gt;   &lt;value&gt;Y&lt;/value&gt; &lt;/prop&gt; </pre>

☞ For more information about server management requests, see [“About server management requests” on page 92](#).

**See also**

- ◆ [“QAnywhere Transmission and Delete Rules” on page 225](#)

**Example**

The following server management request creates a destination alias called simpleGroup with members called client1 and client2\queue11. This example starts the destination alias so that it immediately begins handling messages.

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.qa.group</name>
      <value>Y</value>
    </prop>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.connector.address</name>
      <value>simpleGroup</value>
    </prop>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.connector.nativeConnection</name>
      <value>ianywhere.message.connector.group.GroupConnector</value>
    </prop>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.connector.logLevel</name>
      <value>4</value>
    </prop>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.qa.member.client1</name>
      <value>Y</value>
    </prop>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.qa.member.client2\q11</name>
      <value>Y</value>
    </prop>
  </SetProperty>
</actions>

```

```

    </SetProperty>
  <OpenConnector>
    <client>simpleGroup</client>
  </OpenConnector>
</actions>

```

## Adding and removing members in a destination alias

To add members to a destination alias, create a server management request that specifies the member in a property. The group must be restarted for the member setting to take effect.

The following example adds the member client3 and restarts the group simpleGroup:

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.qa.member.client3</name>
      <value>Y</value>
    </prop>
  </SetProperty>
  <CloseConnector>
    <client>simpleGroup</client>
  </CloseConnector>
  <OpenConnector>
    <client>simpleGroup</client>
  </OpenConnector>
</actions>

```

To remove members from a destination alias, create a server management request that contains a property setting indicating that the member must be removed. The group must be restarted for the member removal setting to take effect.

The following example removes the member client3 and restarts the group simpleGroup:

```

<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <SetProperty>
    <prop>
      <client>simpleGroup</client>
      <name>ianywhere.qa.member.client3</name>
    </prop>
  </SetProperty>
  <CloseConnector>
    <client>simpleGroup</client>
  </CloseConnector>
  <OpenConnector>
    <client>simpleGroup</client>
  </OpenConnector>
</actions>

```

## Monitoring QAnywhere

You can use a server management request to get information about a set of messages. The server compiles the information and sends it back to the client in a message. You can create a one-time message details request or schedule your message details request to happen automatically. In addition, you can specify that your request should be persistent, so that the message is sent even if the server is restarted.

☞ For an overview of how to use server management requests, including how to authenticate and schedule them, see [“About server management requests” on page 92](#).

### Message details requests

To write a server management request for message details, use the `<MessageDetailsRequest>` tag.

A message details request contains one or more `<request>` tags containing all the necessary information to register the request. Specifying more than one `<request>` tag is equivalent to sending multiple separate message details requests.

Use the optional `<replyAddr>` tag to specify the return address for each report generated as a result of the request. If this tag is omitted, the default return address of reports is the reply address of the originating message.

Use a `<requestId>` tag to specify a unique identifier for the request that is included in each report generated as a result of this request. Using different values for this field allows more than one request to be active at the same time. Using the same request ID allows the client to override or delete active requests.

Specify a `<condition>` tag to determine which messages should be included in the report. See [“Condition tag” on page 94](#).

You can also specify a list of details to determine what details of each message should be included in the report. You do this by including a set of empty detail element tags in the request.

You can use the `<persistent>` tag to specify that event details should be made persistent during any server downtime. This tag does not require any data and can be of the form `<persistent/>` or `<persistent></persistent>`.

You can use `<schedule>` to include all the necessary details needed to register a scheduled report. See [“Scheduling server management requests” on page 98](#).

<b><code>&lt;MessageDetailsRequest&gt;</code> sub-tags</b>	<b>Description</b>
<code>&lt;request&gt;</code>	Groups information about a particular request. Specifying more than one <code>&lt;request&gt;</code> tag is equivalent to sending multiple separate server management requests for message information. See below.

**Request tag**

<b>&lt;Request&gt; subtags</b>	<b>Description</b>
<address>	Displays the address of each message.
<condition>	Groups conditions for including a message in the report. See <a href="#">“Condition tag” on page 94</a> .
<contentSize>	Requests the content size of each message.
<customRule>	See <a href="#">“Custom message requests” on page 95</a> .
<expires>	Requests the expiration time of each message.
<kind>	Requests whether the message is text or binary.
<messageId>	Requests the message ID of each message.
<originator>	Requests the originator of each message.
<persistent>	Including this tag indicates that the results of the request should be made persistent in the server database (so that the report is sent even if the server is restarted).
<priority>	Requests the priority of each message.
<property>	Requests a list of all message properties and values for each message.
<statusTime>	Requests the status time of each message.
<replyAddr>	Specifies the return address for each report generated as a result of this request. If this tag is omitted, the default return address of reports is the reply address of the originating message.
<requestId>	This value is a unique identifier for the request and is included in each report generated as a result of this request. Using different values for this field allows more than one request to be active at the same time. Using the same request id allows the client to override or delete active requests.
<schedule>	Including this tag indicates that the report should be generated on a schedule. Subtags of <schedule> identify the schedule on which the report runs.  ☞ See <a href="#">“Scheduling server management requests” on page 98</a> .
<status>	Requests the status of each message.

**MessageDetailsReport tag**

Each Message Details Report is an XML message containing the <MessageDetailsReport> tag, and is composed of a report header followed by optional <message> tags. The header of each report consists of the following tags:

<MessageDetailsReport> subtags	Description
<message>	The body of the report consists of a list of <message> tags whose subtags display the specific details of each message that satisfied the selection criteria. If no messages were selected, or no detail elements were specified in the original request, then no <message> tags will be included in the report. Otherwise, each message will have its own <message> tag.
<messageCount>	The number of messages that satisfy the selection criteria of the request.
<requestId>	The ID of the request that generated the report.
<statusDescription>	A brief description of the reason why this report was generated.
<UTCDateLine>	The time and date that this report was generated.

### Examples

Following is an example of a message details report:

```
<?xml version="1.0" encoding="UTF-8"?>
<MessageDetailsReport>
  <requestId>testReport</requestId>
  <UTCDateLine>Mon Jan 16 15:03:04 EST 2006</UTCDateLine>
  <statusDescription>Scheduled report</statusDescription>
  <messageCount>1</messageCount>
  <message>
    <messageId>ID:26080b8927f83f9722357eab0a0628eb</messageId>
    <status>60</status>
    <property>
      <name>myPropName</name>
      <value>myPropVal</value>
    </property>
  </message>
</MessageDetailsReport>
```

The following condition selects messages following the search criteria: (msgId=ID:144... OR msgId=ID225... ) AND (status=pending) AND (kind=textmessage) AND (contains the property 'myProp' with value 'myVal' )

```
<condition>
  <messageId>ID:144d7e44dc2d7e1d</messageId>
  <messageId>ID:22578sd5dsd99s8e</messageId>
  <status>1</status>
  <kind>text</kind>
  <property>myProp=myVal</property>
</condition>
```

A one-time request is a request that has omitted the <schedule> tag. These requests are used to generate a single report and are deleted as soon as the report has been sent. This request generates a single report that displays the message id, status, and target address of all messages with priority 9 currently on the server.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
```

```
<MessageDetailsRequest>
  <request>
    <requestId>testRequest</client>
    <condition>
      <priority>9</priority>
    </condition>
    <messageId/>
    <status/>
    <address/>
  </request>
</MessageDetailsRequest>
</actions>
```

The following sample message details request generates a report that includes the message ID and message status.

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <MessageDetailsRequest>
    <!-- ... -->
    <messageId />
    <status />
  </MessageDetailsRequest>
</actions>
```

## Monitoring QAnywhere clients

You can use a server management request to obtain a list of clients currently on the server. This list contains clients who are registered on the server, including remote clients, open connectors, and destination aliases.

☞ For an overview of how to use server management requests, including how to authenticate and schedule them, see [“About server management requests” on page 92](#).

To obtain a list of clients, use the <GetClientList> tag in your server management request. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <GetClientList/>   (or <GetClientList></GetClientList> )
</actions>
```

The response that is generated is sent to the reply address of the message containing the request. The response contains a list of <client> tags, each naming one client connected to the server. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<GetClientListResponse>
  <client>ianywhere.server</client>
  <client>ianywhere.connector.myConnector</client>
  <client>myClient</client>
</GetClientListResponse>
```

## Monitoring properties

You can use a server management request to see what properties are set for a client. The response lists only the properties that have been set for the client (not defaults).

☞ For an overview of how to use server management requests, including how to authenticate and schedule them, see [“About server management requests” on page 92](#).

To get a list of properties for a client, use the `<GetProperties>` tag in your server management request. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<actions>
  <GetProperties>
    <client>ianywhere.connector.myConnector</client>
  </GetProperties>
</actions>
```

The response that is generated is sent to the reply address of the message containing the request. The response contains the name of the client and a list of `<prop>` tags, each containing the details of one property. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<GetPropertiesResponse>
  <client>ianywhere.connector.myConnector</client>
  <prop>
    <name>ianywhere.connector.logLevel</name>
    <value>4</value>
  </prop>
  <prop>
    <name>ianywhere.connector.state</name>
    <value>2</value>
  </prop>
</GetPropertiesResponse>
```

Tutorial: Using JMS connectors .....	141

### About this chapter

This chapter describes how to write QAnywhere client applications to exchange messages with external messaging systems that support a JMS interface.

## Introduction

The Java Message Service (JMS) API provides messaging capabilities to Java applications. In addition to exchanging messages among QAnywhere client applications, you can exchange messages with external messaging systems that support a JMS interface. You do this using a specially configured client known as a connector. In a QAnywhere application, the external messaging system is set up to act like a QAnywhere client. It has its own address and configuration.

☞ For more information about the architecture of this approach, see [“Scenario for messaging with external messaging systems”](#) on page 11.

## Setting up JMS connectors

The following steps provide an overview of the tasks required to set up QAnywhere with JMS connectors, assuming that you already have QAnywhere set up.

### ◆ Overview of integrating a QAnywhere application with an external JMS system

1. Create JMS queues using the JMS administration tools for your JMS system. The QAnywhere connector listens on a single JMS queue for JMS messages. You must create this queue if it does not already exist.

☞ See the documentation of your JMS product for information about how to create queues.

2. Open Sybase Central and connect to your server message store.
3. Choose File ► New Connector.

The Connector wizard appears.

4. Ensure that JMS is selected and then select the type of web server you are using. Click Next.
5. In the Connector Names page, enter the following values:

◆ **Connector name** The connector address that a QAnywhere client should use to address the connector.

☞ See “Addressing QAnywhere messages meant for JMS” on page 137.

◆ **Receiver destination** The queue name used by the connector to listen for messages from JMS targeted for QAnywhere clients.

6. In the JNDI Settings page, enter the following values:

◆ **JNDI factory** The factory name used to access the external JMS JNDI name service.

◆ **Name service URL** The URL to access the JMS JNDI name service.

◆ **User name** The authentication name to connect to the external JMS JNDI name service.

◆ **Password** The authentication password to connect to the external JMS JNDI name service.

7. In the JMS Queue Settings page, enter the following values:

◆ **Queue factory** The external JMS provider queue factory name.

◆ **User name** The user ID to connect to the external JMS queue connection.

◆ **Password** The password to connect to the external JMS queue connection.

8. In the JMS Topic Settings page, enter the following values:

◆ **Topic factory** The external JMS provider topic factory name.

◆ **User name** The user ID to connect to the external JMS topic connection.

◆ **Password** The password to connect to the external JMS topic connection.

9. Click Finish.

You are prompted to add the client JAR files in the `mlsrv10` command line.

10. Start the MobiLink server with a connection to the server message store and the `-sl java` option.

☞ See “[Starting the MobiLink server for JMS integration](#)” on page 131.

11. To set additional options on your JMS connector, right-click the connector you just created and choose properties; or you can use server management requests.

☞ For a list of available properties, see “[JMS connector properties](#)” on page 132.

For information about how to set connector properties with server management requests, see “[Administering connectors](#)” on page 104.

### ◆ To send messages

1. To send a message from an application in your QAnywhere system to the external messaging system, create a QAnywhere message and send it to **`connector-address\JMS-queue-name`**.

☞ See “[Addressing QAnywhere messages meant for JMS](#)” on page 137.

2. To send a message from the external messaging system to an application in your QAnywhere system:

◆ Create a JMS message.

◆ Set the `ias_ToAddress` property to the QAnywhere **`id\queue`** (where *id* is the ID of your client message store and *queue* is your application queue name).

◆ Put the message in the JMS queue.

☞ See “[Addressing JMS messages meant for QAnywhere](#)” on page 139.

### Other resources for getting started

◆ QAnywhere JMS samples are installed to `samples-dir\QAnywhere\connectors`. (For information about `samples-dir`, see “[The samples directory](#)” [[SQL Anywhere Server - Database Administration](#)].)

## Starting the MobiLink server for JMS integration

To exchange messages with an external messaging system that supports a JMS interface, you must start the MobiLink server (mlsrv10) with the following options:

◆ **-c *connection-string*** To connect to the server message store.

☞ See “-c option” [*MobiLink - Server Administration*].

◆ **-m** To enable QAnywhere messaging.

◆ **-sl java (-cp "*jarfile.jar*")** To add the client jar files required to use the external JMS provider.

☞ See “-sl java option” [*MobiLink - Server Administration*].

### Example

The following example starts a MobiLink server using a JMS client library called *jmsclient.jar* (in the current working directory) and the QAnywhere sample database as a message store. The command should be entered all on one line.

```
mlsrv10 -sl java(-cp "jmsclient.jar")  
          -m -c "QAnywhere 10.0 Demo" ...
```

## JMS connector properties

You use JMS connector properties to specify connection information with the JMS system. They configure a connector to a third party JMS messaging system such as BEA WebLogic or Sybase EAServer.

You can set and/or view properties in several places:

- ◆ Sybase Central Connector Wizard.

See [“Setting up JMS connectors” on page 129](#).

- ◆ Sybase Central Connector Properties dialog.
- ◆ Server management requests.

See [“Creating and configuring connectors” on page 104](#).

- ◆ The `ml_qa_global_props` MobiLink system table.

See [“ml\\_qa\\_global\\_props” \[MobiLink - Server Administration\]](#).

The following properties are used to configure the JMS connector:

- ◆ **ianywhere.connector.nativeConnection** The Java class that implements the connector. It is for QAnywhere internal use only, and should not be deleted or modified.
- ◆ **ianywhere.connector.id (deprecated)** An identifier that uniquely identifies the connector. The default is the value of the connector property `ianywhere.connector.address`.
- ◆ **ianywhere.connector.address** The connector address that a QAnywhere client should use to address the connector. This address is also used to prefix all logged error, warning, and informational messages appearing in the server console for this connector.

☞ For more information, see [“Addressing QAnywhere messages meant for JMS” on page 137](#).

In Sybase Central, set this property in the Connector wizard, Connector Names page, Connector Name field.

- ◆ **ianywhere.connector.incoming.retry.max** The maximum number of times the connector will retry transferring a JMS message to a QAnywhere message store before giving up. After the maximum number of failed attempts, the JMS message is re-addressed to the `ianywhere.connector.jms.deadMessageDestination` property value. The default is -1, which means that the connector will never give up.
- ◆ **ianywhere.connector.outgoing.deadMessageAddress** The address that a message is sent to when it cannot be processed. For example, if a message contains a JMS address that is malformed or unknown, the message is marked as unreceivable and a copy of the message is sent to the dead message address.

If no dead message address is specified, the message is marked as unreceivable but no copy of the message is sent.

In Sybase Central, you can set this property in the connector properties dialog Properties tab, by clicking New.

- ◆ **ianywhere.connector.logLevel** The amount of connector information displayed in the MobiLink server console and log file. Values for the log level are as follows:

- ◆ **1** Log error messages.
- ◆ **2** Log error and warning messages.
- ◆ **3** Log error, warning, and information messages.
- ◆ **4** Log error, warning, information, and debug messages.

In Sybase Central, set this property on the connector properties dialog, on the General tab, in the Logging Level section.

You can also set this property for all connectors. To do this in Sybase Central, connect to a server message store and choose the task Change Properties of this Message Store. Open the Server Properties tab.

- ◆ **ianywhere.connector.compressionLevel** The default message compression factor of messages received from JMS: an integer between 0 and 9, with 0 indicating no compression and 9 indicating maximum compression.

In Sybase Central, set this property on the connector properties dialog, on the General tab, in the Compression Level section.

You can also set this property for all connectors. To do this in Sybase Central, connect to a server message store, choose the task Change Properties of this Message Store, and open the Server Properties tab.

- ◆ **ianywhere.connector.jms.deadMessageDestination** The address that a JMS message is sent to when it cannot be converted to a QAnywhere message. This might occur if the JMS message is an instance of an unsupported class, if the JMS message does not specify a QAnywhere address, if an unexpected JMS provider exception occurs, or if an unexpected QAnywhere exception occurs.

In Sybase Central, set this property on the connector properties dialog, on the JMS tab, in the Other section, in the Dead Message Destination field.

- ◆ **ianywhere.connector.outgoing.retry.max** The default number of retries for messages going from QAnywhere to the external messaging system. The default value is 5. Specify 0 to have the connector retry forever.

In Sybase Central, you can set this property in the connector properties dialog, Properties tab, by clicking New.

- ◆ **ianywhere.connector.runtimeError.retry.max** The number of times a connector retries a message that causes a RuntimeException. If a dead message queue is specified, the message is put in that queue. Otherwise, the message is marked as unreceivable and skipped. Specify a value of 0 to have the server never give up.

- ◆ **ianywhere.connector.startupType** Startup types can be automatic, manual, or disabled.

- ◆ **xjms.jndi.authName** The authentication name to connect to the external JMS JNDI name service.

In Sybase Central, set this property in the Connector wizard, JNDI Settings page, User Name field; or on the connector properties dialog on the JMS tab, JNDI section, User Name field.

- ◆ **xjms.jndi.factory** The factory name used to access the external JMS JNDI name service.

In Sybase Central, set this property in the Connector wizard, JNDI Settings page, Password field; or on the connector properties dialog on the JMS tab, JNDI section, Password field.

- ◆ **xjms.jndi.password.e** The authentication password to connect to the external JMS JNDI name service.

In Sybase Central, set this property in the Connector wizard, JNDI Settings page, Name Service URL field; or on the connector properties dialog on the JMS tab, JNDI section, URL field.

- ◆ **xjms.jndi.url** The URL to access the JMS JNDI name service.

In Sybase Central, set this property in the Connector wizard, JNDI Settings page, Name Service URL field; or on the connector properties dialog on the JMS tab, JNDI section, URL field.

- ◆ **xjms.password.e** The authentication password to connect to the external JMS provider.

- ◆ **xjms.queueConnectionAuthName** The user ID to connect to the external JMS queue connection.

In Sybase Central, set this property in the Connector wizard, JMS Queue Settings page, User Name field; or on the connector properties dialog on the JMS tab, Queue section, User Name field.

- ◆ **xjms.queueConnectionPassword.e** The password to connect to the external JMS queue connection.

In Sybase Central, set this property in the Connector wizard, JMS Queue Settings page, Password field; or on the connector properties dialog on the JMS tab, Queue section, Password field.

- ◆ **xjms.queueFactory** The external JMS provider queue factory name.

In Sybase Central, set this property in the Connector wizard, JMS Queue Settings page, Queue Factory field; or on the connector properties dialog on the JMS tab, Queue section, Queue Factory field.

- ◆ **xjms.receiveDestination** The queue name used by the connector to listen for messages from JMS targeted for QAnywhere clients.

In Sybase Central, set this property in the Connector wizard, Connector Names page, Receiver Destination field.

- ◆ **xjms.topicFactory** The external JMS provider topic factory name.

In Sybase Central, set this property in the Connector wizard, JMS Topic Settings page, Topic Factory field; or on the connector properties dialog on the JMS tab, Topic section, Topic Factory field.

- ◆ **xjms.topicConnectionAuthName** The user ID to connect to the external JMS topic connection.

In Sybase Central, set this property in the Connector wizard, JMS Topic Settings page, User Name field; or on the connector properties dialog on the JMS tab, Topic section, User Name field.

- ◆ **xjms.topicConnectionPassword.e** The password to connect to the external JMS topic connection.

In Sybase Central, set this property in the Connector wizard, JMS Topic Settings page, Password field; or on the connector properties dialog on the JMS tab, Topic section, Password field.

## Configuring multiple connectors

QAnywhere can connect to multiple JMS message systems by defining a JMS connector for each JMS system. The only property value that must be unique among the configured connectors is `ianywhere.connector.address`.

The `ianywhere.connector.address` property is the address prefix that QAnywhere clients must specify to address messages meant for the JMS system.

☞ For information about specifying the address of QAnywhere clients, see [“Addressing QAnywhere messages meant for JMS” on page 137](#).

☞ For information about the connector properties, see [“JMS connector properties” on page 132](#).

☞ For information about configuring connectors, see [“Creating and configuring connectors” on page 104](#).

## Addressing QAnywhere messages meant for JMS

A QAnywhere client can send a message to a JMS system by setting the address to the following value:

*connector-address* \*JMS-queue-name*

The *connector-address* is the value of the connector property `ianywhere.connector.address`, while *JMS-queue-name* is the name used to look up the JMS queue or topic using the Java Naming and Directory Interface.

If your *JMS-queue-name* contains a backslash, you must escape the backslash with another backslash. For example, a queue called `qq` in the context `ss` should be specified as `ss\\qq`.

```
// C# example
QAMessage msg;
QAManager mgr;
...
mgr.PutMessage( @"ianywhere.connector.wsmqfs\\ss\\qq", msg );

// C++ example
QAManagerBase *mgr;
QATextMessage *msg;
...
mgr->putMessage( "ianywhere.connector.easerver\\ss\\\\"qq", msg );
```

### Example

For example, if the `ianywhere.connector.address` is set to `ianywhere.connector.easerver` and the JMS queue name is `myqueue`, then the code to set the address would be:

```
// C# example
QAManagerBase mgr;
QAMessage msg;
// Initialize the manager.
...
msg = mgr.CreateTextMessage();
// Set the message content.
...
mgr.PutMessage(@"ianywhere.connector.easerver\myqueue", msg );

// C++ example
QAManagerBase *mgr;
QATextMessage *msg;
// Initialize the manager.
...
msg = mgr.createTextMessage();
// Set the message content.
...
mgr->putMessage( "ianywhere.connector.easerver\myqueue", msg );
```

### See also

- ◆ [“QAnywhere message addresses” on page 50](#)
- ◆ [“JMS connector properties” on page 132](#)

## Mapping QAnywhere messages on to JMS messages

QAnywhere messages are mapped naturally on to JMS messages.

### QAnywhere message content

QAnywhere	JMS	Remarks
QATextMessage	javax.jms.TextMessage	message text copied as Unicode
QABinaryMessage	javax.jms.BytesMessage	message bytes copied exactly

### QAnywhere built-in headers

The following table describes the mapping of built-in headers. In C++ and JMS, these are method names; for example, Address is called getAddress() or setAddress() for QAnywhere, and getJMSDestination() or setJMSDestination() for JMS. In .NET, these are properties with the exact name given below; for example, Address is Address.

QAnywhere	JMS	Remarks
Address	JMSDestination and JMS property ias_ToAddress	If the destination contains a backslash, you must escape it with a second backslash.  Only the JMS part of the address is mapped to the Destination. Under rare circumstances, in the case of a message looping back into QAnywhere, there may be an additional QAnywhere address suffix. This is put in ias_ToAddress.
Expiration	JMSExpiration	
InReplyToID	N/A	Not mapped.
MessageID	N/A	Not mapped.
Priority	JMSPriority	
Redelivered	N/A	Not mapped.
ReplyToAddress	JMS property ias_ReplyToAddress	Mapped to JMS property.
Connector's xjms.receiveDestination property value	JMSReplyTo	ReplyTo set to Destination used by connector to receive JMS messages.
Timestamp	N/A	Not mapped.

## QAnywhere properties

QAnywhere properties are all mapped naturally to JMS properties, preserving type, with the following exception: if the QAnywhere message has a property called JMSType, then this is mapped to the JMS header property JMSType.

## Addressing JMS messages meant for QAnywhere

A JMS client can send a message to a QAnywhere client by setting the JMS message property `ias_ToAddress` to the QAnywhere address, and then sending the message to the JMS Destination corresponding to the connector property `xjms.receiveDestination`.

☞ For more information, see [“QAnywhere message addresses” on page 50](#).

### Example

For example, to send a message to the QAnywhere address "qaddr" (where the connector setting of `xjms.receiveDestination` is "qanywhere\_receive"):

```
import javax.jms.*;
...
try {
    QueueSession session;
    QueueSender sender;
    TextMessage mgr;
    Queue connectorQueue;
    // Initialize the session.
    ...
    connectorQueue = session.createQueue( "qanywhere_receive" );
    sender = session.createSender( connectorQueue );
    msg = session.createTextMessage();
    msg.setStringProperty( "ias_ToAddress", "qaddr" );
    // Set the message content.
    ...
    sender.send( msg );
} catch( JMSException e ) {
    // Handle the exception
    ...
}
```

## Mapping JMS messages on to QAnywhere messages

JMS messages are mapped naturally on to QAnywhere messages.

### JMS message content

JMS	QAnywhere	Remarks
<code>javax.jms.TextMessage</code>	<code>QATextMessage</code>	Message text copied as Unicode
<code>javax.jms.BytesMessage</code>	<code>QABinaryMessage</code>	Message bytes copied exactly
<code>javax.jms.StreamMessage</code>	N/A	Not supported

JMS	QAnywhere	Remarks
javax.jms.MapMessage	N/A	Not supported
javax.jms.ObjectMessage	N/A	Not supported

### JMS built-in headers

The following table describes the mapping of built-in headers. In C++ and JMS, these are method names; for example, Address is called getAddress() or setAddress() for QAnywhere, and getJMSDestination() or setJMSDestination() for JMS. In .NET, these are properties with the exact name given below; for example, Address is Address.

JMS	QAnywhere	Remarks
JMS Destination	N/A	The JMS destination must be set to the queue specified in the connector property xjms.receiveDestination.
JMS Expiration	Expiration	
JMS CorrelationID	InReplyToID	
JMS MessageID	N/A	Not mapped.
JMS Priority	Priority	
JMS Redelivered	N/A	Not mapped.
JMS ReplyTo and connector's ianywhere.connector.address property value	ReplyToAddress	The connector address is concatenated with the JMS ReplyTo Destination name delimited by '\.
JMS DeliveryMode	N/A	Not mapped.
JMS Type	QAnywhere message property JMSType	
JMS Timestamp	N/A	Not mapped.

### JMS properties

JMS properties are all mapped naturally to QAnywhere properties, preserving type, with a few exceptions. The QAnywhere Address property is set from the value of the JMS message property ias\_ToAddress. If the JMS message property ias\_ReplyToAddress is set, then the QAnywhere ReplyToAddress is additionally suffixed with this value delimited by a '\.

## Tutorial: Using JMS connectors

A JMS connector provides connectivity between a JMS message system and QAnywhere. This tutorial sends messages between a JMS system and QAnywhere.

### About the tutorial

This tutorial starts a JMS connector and sends a message from a JMS client to a QAnywhere client.

### Required software

For this tutorial, you need access to a JMS provider and basic knowledge of how to configure it. In addition, you need JDK version 1.3.1 or later and any JAR files required by a JMS client of the JMS provider.

## Lesson 1: Start a JMS connector

### ◆ To prepare your JMS provider

1. Start your JMS server.

☞ See the documentation for your JMS server.

2. Create two queues within your JMS server: `qa_testmessage` and `qa_receive`. You may need to restart your JMS server after creating the queues.

☞ See the documentation for your JMS server.

### ◆ To start QAnywhere client and server components

1. Create a directory to hold the files you create for this tutorial. For example, `c:\JMSTestMessage`. Navigate to that directory.

2. Create a QAnywhere connector:

◆ In Sybase Central, choose File ► New Connector and following the prompts in the Connector wizard.

For more information, see [“Setting up JMS connectors” on page 129](#).

3. Start the MobiLink server for messaging:

From the Windows Start menu, choose Programs ► SQL Anywhere 10 ► MobiLink ► MobiLink with Messaging Sample.

Alternatively, at a command prompt, navigate to `samples-dir\QAnywhere\server` and type the following command:

```
mlsrv10 -m -c "dsn=QAnywhere 10.0 Demo" -sl java(-cp "jarfiles") -vcrs -zu
+
```

4. Start the QAnywhere Agent:

From the Start menu, choose Programs ► SQL Anywhere 10 ► QAnywhere ► Agent for Client1 Sample.

5. Start the TestMessage sample:

From the Windows Start menu, choose Programs ► SQL Anywhere 10 ► QAnywhere ► TestMessage for Client1 Sample.

### ◆ To start the Java version of the TestMessage client

1. At a command prompt, navigate to *Samples\QAnywhere\connectors\JMS\TestMessage* and type the following:

```
java -cp .;JMS-client-jar-files ianywhere.message.samples.TestMessage
```

where *JMS-client-jar-files* is a semi-colon delimited list of jar files that are required to access the JMS server. See your JMS server documentation for details.

For Sybase EAServer, this command would be:

```
java -cp .;path\easclient.jar;path\easj2ee.jar  
ianywhere.message.samples.TestMessage
```

where *path* is the location of the jar files.

#### Note

On Unix, use colons instead of semicolons.

2. Move the JMS TestMessage window to the right side of your screen under the existing TestMessage for Client1 window.

## Lesson 2: Send a message from a JMS client to a QAnywhere client

### ◆ To send a message from a JMS client to a QAnywhere client

1. From the JMS TestMessage Message menu, choose New.  
The New Message window appears.
2. In the To field, enter the client message store ID of client1.
3. Fill out the Subject and Message fields with sample text, and click Send.
4. Within a short time a message box appears, indicating that a message has been received by TestMessage for Client2.

## Tutorial cleanup

Shut down TestMessage clients, the QAnywhere Agent, and the MobiLink server.

---

### About this chapter

This chapter describes the syntax and options of the QAnywhere Agent, qaagent.

☞ For an overview of how to run the QAnywhere Agent, see [“Running the QAnywhere Agent” on page 35](#).

## qaagent syntax

Use the QAnywhere Agent to send and receive messages for all QAnywhere applications on a single client device.

### Syntax

**qaagent** [ *option ...* ]

Option	Description
<b>@data</b>	Reads options from the specified environment variable or configuration file. See “ <a href="#">@data option</a> ” on page 147.
<b>-c</b> <i>connection-string</i>	Specifies a connection string to the client message store. See “ <a href="#">-c option</a> ” on page 148.
<b>-id</b> <i>id</i>	Specifies the ID of the client message store that the QAnywhere Agent is to connect to. See “ <a href="#">-id option</a> ” on page 152.
<b>-iu</b> <i>upload-size</i>	Specifies the maximum size of an upload to use during a message transmission . See “ <a href="#">-iu option</a> ” on page 153.
<b>-lp</b> <i>number</i>	Specifies the port on which the Listener listens for notifications from the MobiLink server. The default is 5001. See “ <a href="#">-lp option</a> ” on page 154.
<b>-mp</b> <i>password</i>	Specifies a new password for the MobiLink user. See “ <a href="#">-mp option</a> ” on page 156.
<b>-mp</b> <i>password</i>	Specifies the MobiLink password for the ID being synchronized. See “ <a href="#">-mp option</a> ” on page 156.
<b>-mu</b> <i>username</i>	Specifies the MobiLink user. See “ <a href="#">-mu option</a> ” on page 157.
<b>-o</b> <i>logfile</i>	Specifies a file to which to log output messages. See “ <a href="#">-o option</a> ” on page 158.
<b>-on</b> <i>size</i>	Specifies a maximum size for the QAnywhere Agent message log file, after which the file is renamed with the extension .old and a new file is started. See “ <a href="#">-on option</a> ” on page 159.
<b>-os</b> <i>size</i>	Specifies a maximum size for the QAnywhere Agent message log file, after which a new log file with a new name is created and used. See “ <a href="#">-os option</a> ” on page 160.
<b>-ot</b> <i>logfile</i>	Specifies a file to which to log output messages. See “ <a href="#">-ot option</a> ” on page 161.
<b>-pc</b> {+ -}	Enables persistent connections for message transmission. See “ <a href="#">-pc option</a> ” on page 162.
<b>-policy</b> <i>policy-type</i>	Specifies the transmission policy used by the QAnywhere Agent. See “ <a href="#">-policy option</a> ” on page 163.

Option	Description
<b>-push mode</b>	Enables or disables push notifications. The default is enabled. See <a href="#">“-push option” on page 165</a> .
<b>-q</b>	Starts the QAnywhere Agent in quiet mode with the window minimized in the system tray. See <a href="#">“-q option” on page 167</a> .
<b>-qi</b>	Starts the QAnywhere Agent in quiet mode with the window completely hidden. See <a href="#">“-qi option” on page 168</a> .
<b>-si</b>	Initializes the database for use as a client message store. See <a href="#">“-si option” on page 169</a> .
<b>-su</b>	Upgrades a client message store to the current version without running dbunload/reload. See <a href="#">“-su option” on page 170</a> .
<b>-sur</b>	Upgrades a client message store to the current version and performs dbunload/reload of the message store. See <a href="#">“-sur option” on page 171</a> .
<b>-v [levels]</b>	Specifies a level of verbosity. See <a href="#">“-v option” on page 172</a> .
<b>-x { http tcpip tls https } [ (keyword=value;... ) ]</b>	Specifies protocol options for communication with the MobiLink server. See <a href="#">“-x option” on page 173</a> .

## Usage

For usage information about qaagent, see [“Running the QAnywhere Agent” on page 35](#).

## @data option

### Function

Reads options from the specified environment variable or configuration file.

### Syntax

**qaagent** @{ *filename* | *environment-variable* } ...

### Remarks

With this option, you can put command line options in an environment variable or configuration file. If both exist with the name you specify, the environment variable is used.

☞ For more information about configuration files, see [“Using configuration files” \[SQL Anywhere Server - Database Administration\]](#).

If you want to protect passwords or other information in the configuration file, you can use the File Hiding utility to obfuscate the contents of the configuration file.

This option is useful for Windows CE because command lines in shortcuts are limited to 256 characters.

☞ See [“File Hiding utility \(dbfhide\)” \[SQL Anywhere Server - Database Administration\]](#).

### Sybase Central equivalent

The QAnywhere plug-in to Sybase Central has a task called Create An Agent Command File. When you choose it, you are prompted to enter a file name and then a Properties dialog appears that helps you enter the command information. The file that is produced has a *.qaa* extension. The *.qaa* file extension is a Sybase Central convention; this file is the same as what you would create for the @data option. You can use the command file created by Sybase Central as your @data configuration file.

## -c option

### Function

Specify a connection string to the client message store.

### Syntax

```
qaagent -c connection-string ...
```

### Defaults

Connection parameter	Default value
uid	ml_qa_user
pwd	qanywhere

### Remarks

The connection string must specify connection parameters in the form *keyword=value*, separated by semicolons, with no spaces between parameters.

DSNs are not typically used on client devices. ODBC is not used by qaagent.

☞ For a complete list of connection parameters, see [“Connection parameters” \[SQL Anywhere Server - Database Administration\]](#).

Following are some of the connection parameters you may need to use:

- ◆ **dbf=filename** Connect to a message store with the specified filename.
- ◆ **dbn=database-name** If the client message store is already running when the QAnywhere Agent starts, you can connect to it by specifying a database name rather than a database file.
- ◆ **eng=server-name** If you want to use a database server that is already running, use this option to specify the server name. The default value is the name of the database.
- ◆ **uid=user** Specify a database user ID to connect to the client message store. This parameter is required if you change the defaults.
- ◆ **pwd=password** Specify the password for the database user ID. This is required if you change the defaults.
- ◆ **dbkey=key** If the client message store is encrypted using strong encryption, specify the encryption key required to access the database.

### See also

- ◆ [“Connection parameters” \[SQL Anywhere Server - Database Administration\]](#)
- ◆ [“Connecting to a Database” \[SQL Anywhere Server - Database Administration\]](#)

**Example**

```
qaagent -id Device1 -c "DBF=qanyclient.db" -x tcpip(host=hostname) -policy  
automatic
```

## -fd option

### Function

This option, when specified in conjunction with the -fr option, specifies the delay between attempts to connect to the MobiLink server.

### Syntax

```
qaagent -fd seconds ...
```

### Default

- ◆ If you specify -fr and do not specify -fd, the delay is 0 (no delay between retry attempts).
- ◆ If you do not specify -fr, the default is no retry attempts.

### Remarks

You must use this option with the -fr option. The -fr option specifies how many times to retry the connection to the primary server, and the -fd option specifies the delay between retry attempts.

This option is typically used when you specify failover MobiLink servers with the -x option. By default when you set up a failover MobiLink server, the QAnywhere Agent tries an alternate server immediately upon a failure to reach the primary server. You can use the -fr option to cause the QAnywhere Agent to try the primary server again before going to the alternate server, and you can use the -fd option to specify the amount of time between retries of the primary server.

It is recommended that you set this option to 10 seconds or less.

### See also

- ◆ [“-fr option” on page 151](#)
- ◆ [“-x option” on page 173](#)
- ◆ [“Setting up a failover mechanism” on page 42](#)

## -fr option

### Function

This option specifies the number of times that the QAnywhere Agent should retry the connection to the primary MobiLink server.

### Syntax

**qaagent -fr** *number-of-retries* ...

### Default

**0** (the QAnywhere Agent will not attempt to retry the primary MobiLink server)

### Remarks

By default, if the QAnywhere Agent is not able to connect to the MobiLink server, there is no error and messages are not sent. This option specifies that the QAnywhere Agent should retry the connection to the MobiLink server, and specifies the number of times that it should retry before trying an alternate server or issuing an error if you have not specified an alternate server.

This option is typically used when you specify failover MobiLink servers with the -x option. By default when you set up a failover MobiLink server, the QAnywhere Agent tries an alternate server immediately upon a failure to reach the primary server. This option causes the QAnywhere Agent to try the primary server again before going to the alternate server.

In addition, you can use the -fd option to specify the amount of time between retries of the primary server.

### See also

- ◆ [“-fd option” on page 150](#)
- ◆ [“-x option” on page 173](#)
- ◆ [“Setting up a failover mechanism” on page 42](#)

## -id option

### Function

Specify the ID of the client message store that the QAnywhere Agent is to connect to.

### Syntax

```
qaagent -id id ...
```

### Default

The default value of the ID is the device name on which the Agent is running. In some cases, device names may not be unique, in which case you must use the -id option.

### Remarks

Each client message store is represented by a unique sequence of characters called the message store ID. If you do not supply an ID when you first connect to the message store, the default is the device name. On subsequent connections, you must always specify the same message store ID with the -id option.

The message store ID corresponds to the MobiLink remote ID. It is required because in all MobiLink applications, each remote database must have a unique ID.

 For more information, see [“Creating and registering MobiLink users” \[MobiLink - Client Administration\]](#).

If you are starting a second instance of the qaagent on a device, the -id option must be used to specify a unique message store ID.

You cannot use the following characters in an ID:

- ◆ double quotes
- ◆ control characters
- ◆ double backslashes

The following additional constraints apply:

- ◆ You can use a single backslash only if it is used as an escape character.
- ◆ If your client message store database has the quoted\_identifier database option set to Off (not the default), then your ID can only include alphanumeric characters and underscores, at signs, pounds, and dollar signs.

### See also

- ◆ [“About MobiLink users” \[MobiLink - Client Administration\]](#)
- ◆ [“Setting up the client message store” on page 33](#)

## -iu option

### Function

Specifies the increment upload size.

### Syntax

**qaagent -iu** *upload-size* [ **K** | **M** ] ...

### Default

256K.

### Remarks

This option specifies the size in bytes of the upload part of a message transmission. Use the suffix k or m to specify units of kilobytes or megabytes, respectively.

When the QAnywhere Agent starts, it assigns the value specified by this option to the `ias_MaxUploadSize` message store property. This message store property defines an upper bound on the size of an upload. When a transmission is triggered, the Agent tags messages for delivery to the server until the total size of all messages reaches the limit set with this option. When the limit is reached, these messages are sent to the server. As long as the messages arrive at the server and an acknowledgement is successfully sent from the server to the client, these messages are considered to be successfully delivered, even if the download phase of the transmission fails. The Agent continues sending batches of messages to the server until all queued messages have been delivered. Transmission rules are re-executed after each batch of messages is transmitted so that if a high priority messages gets queued during a transmission, it will jump to the front of the queue.

An upload will always contain at least one message (if there are messages queued for delivery) and messages will not be split. Therefore, the incremental upload size is an approximation, and it will be a poor approximation if there is a message to be uploaded that is many times larger than the incremental upload size.

### See also

- ◆ `ias_MaxUploadSize` in [“Pre-defined client message store properties” on page 215](#)

## **-lp option**

### **Function**

Specifies the Listener port.

### **Syntax**

**qaagent -lp** *number* ...

### **Default**

5001.

### **Remarks**

The port number on which the Listener listens for UDP notifications from the MobiLink server. Notifications are used to inform the QAnywhere Agent that a message is waiting.

A UDP listener port is only established if the Agent is started with the `-push disconnected` option.

### **See also**

- ◆ [“Scenario for messaging with push notifications” on page 9](#)
- ◆ [“-push option” on page 165](#)

## -mn option

### Function

Specify a new password for the MobiLink user.

### Syntax

**qaagent -mp** *password* ...

### Default

None.

### Remarks

Use to change the password.

### See also

- ◆ [“MobiLink Users” \[MobiLink - Client Administration\]](#)
- ◆ [“-mp option” on page 156](#)
- ◆ [“-mu option” on page 157](#)

## **-mp option**

### **Function**

Specify the MobiLink password for the MobiLink user.

### **Syntax**

**qaagent -mp** *password* ...

### **Default**

None.

### **Remarks**

If the MobiLink server requires user authentication, use -mp to supply the MobiLink password.

### **See also**

- ◆ [“MobiLink Users” \[MobiLink - Client Administration\]](#)
- ◆ [“-mu option” on page 157](#)

## -mu option

### Function

Specify the MobiLink user.

### Syntax

```
qaagent -mu username ...
```

### Default

The client message store ID.

### Remarks

The MobiLink user is used for authentication with the MobiLink server.

If you specify a user name that does not exist, it is created for you.

All MobiLink user names must be registered in the server message store. See [“Registering client user names” on page 31](#).

### See also

- ◆ [“MobiLink Users” \[MobiLink - Client Administration\]](#)
- ◆ [“-id option” on page 152](#)
- ◆ [“-mp option” on page 156](#)
- ◆ [“Remote IDs” \[MobiLink - Client Administration\]](#)

## -o option

### Function

Sends output to a log file.

### Syntax

**qaagent -o logfile ...**

### Default

None.

### Remarks

The QAnywhere Agent logs output to the file name that you specify. If the file already exists, new log information is appended to the file. The SQL Anywhere synchronization client (dbmlsync) logs output to a file with the same name, but including the suffix *\_sync*. The Listener utility (dbsln) logs output to a file with the same name, but including the suffix *\_lsn*.

For example, if you specify the log file *c:\tmp\mylog.out*, then qaagent logs to *c:\tmp\mylog.out*, dbmlsync logs to *c:\tmp\mylog\_sync.out*, and dbsln logs to *c:\tmp\mylog\_lsn.out*.

### See also

- ◆ [“-ot option” on page 161](#)
- ◆ [“-on option” on page 159](#)
- ◆ [“-os option” on page 160](#)
- ◆ [“-v option” on page 172](#)

## -on option

### Function

Specifies a maximum size for the QAnywhere Agent message log file, after which the file is renamed with the extension *.old* and a new file is started.

### Syntax

**qaagent** **-on** *size* [ **k** | **m** ]...

### Default

None.

### Description

The *size* is the maximum file size for the output log, in bytes. Use the suffix **k** or **m** to specify units of kilobytes or megabytes, respectively. The minimum size limit is 10KB.

When the log file reaches the specified size, the QAnywhere Agent renames the output file with the extension *.old*, and starts a new one with the original name.

#### Notes

If the *.old* file already exists, it is overwritten. To avoid losing old log files, use the **-os** option instead. This option cannot be used with the **-os** option.

### See also

- ◆ [“-o option” on page 158](#)
- ◆ [“-ot option” on page 161](#)
- ◆ [“-os option” on page 160](#)
- ◆ [“-v option” on page 172](#)

## -os option

### Function

Specifies a maximum size for the QAnywhere Agent message log file, after which a new log file with a new name is created and used.

### Syntax

```
qaagent -os size [ k | m ] ...
```

### Default

None.

### Description

The *size* is the maximum file size for logging output messages. The default units is bytes. Use the suffix *k* or *m* to specify units of kilobytes or megabytes, respectively. The minimum size limit is 10K.

Before the QAnywhere Agent logs output messages to a file, it checks the current file size. If the log message will make the file size exceed the specified size, the QAnywhere Agent renames the message log file to *yymmddxx.mls*. In this instance, *xx* are sequential characters ranging from 00 to 99, and *yymmdd* represents the current year, month, and day.

You can use this option to prune old message log files to free up disk space. The latest output is always appended to the file specified by *-o* or *-ot*.

#### Note

This option cannot be used with the *-on* option.

### See also

- ◆ [“-o option” on page 158](#)
- ◆ [“-ot option” on page 161](#)
- ◆ [“-on option” on page 159](#)
- ◆ [“-v option” on page 172](#)

## -ot option

### Function

Truncates the log file and appends output messages to it.

### Syntax

**qaagent -ot logfile ...**

### Default

None.

### Remarks

The QAnywhere Agent logs output to the file name that you specify. If the file exists, it is first truncated to a size of 0. The SQL Anywhere synchronization client (dbmlsync) logs output to a file with the same name, but including the suffix *\_sync*. The Listener utility (dbsln) logs output to a file with the same name, but including the suffix *\_lsn*.

For example, if you specify the log file *c:\tmp\mylog.out*, then qaagent logs to *c:\tmp\mylog.out*, dbmlsync logs to *c:\tmp\mylog\_sync.out*, and dbsln logs to *c:\tmp\mylog\_lsn.out*.

### See also

- ◆ [“-o option” on page 158](#)
- ◆ [“-on option” on page 159](#)
- ◆ [“-os option” on page 160](#)
- ◆ [“-v option” on page 172](#)

## -pc option

### Function

Maintain a persistent connection to the MobiLink server between synchronizations.

### Syntax

```
qaagent -pc { + | - } ...
```

### Default

-pc-

### Remarks

Enabling persistent connections (-pc+) is useful when network coverage is good and there is heavy message traffic over QAnywhere. In this scenario, you can reduce the network overhead of setting up and taking down a TCP/IP connection every time a message transmission occurs.

Disabling persistent connections (-pc-) is useful in the following scenarios when the client device has a public IP address and is reachable by UDP or SMS:

- ◆ The client device is using dial-up networking and connection time charges are an issue.
- ◆ There is light message traffic over QAnywhere. Persistent TCP/IP connections consume network server resources, and so could have an impact on scalability.
- ◆ The client device network coverage is unreliable. You can use the automatic policy to transmit messages when connection is possible. Trying to maintain persistent connections in this environment is not useful and can waste CPU resources.

### See also

- ◆ [“-push option” on page 165](#)
- ◆ [“-pc option” \[MobiLink - Client Administration\]](#)

---

## -policy option

### Function

Specifies a policy that determines when message transmission occurs.

### Syntax

```
qaagent -policy policy-type ...
```

*policy-type*: **ondemand** | **scheduled**[ *interval-in-seconds* ] | **automatic** | *rules-file*

### Defaults

- ◆ The default policy type is **automatic**.
- ◆ The default interval for scheduled policies is 900 seconds (15 minutes).

### Remarks

QAnywhere uses a policy to determine when message transmission occurs. The *policy-type* can be one of the following values:

- ◆ **ondemand** Only transmit messages when the QAnywhere client application makes the appropriate method call.

The QAManager PutMessage() method causes messages to be queued locally. These messages are not transmitted to the server until the QAManager TriggerSendReceive() method is called. Similarly, messages waiting on the server are not sent to the client until TriggerSendReceive() is called by the client.

When using the ondemand policy, the application is responsible for causing a message transmission to occur when it receives a push notification from the server. A push notification causes a system message to be delivered to the QAnywhere client. In your application, you may choose to respond to this system message by calling TriggerSendReceive().

☞ For an example, see [“System queue” on page 51](#).

- ◆ **scheduled** Transmit messages at a specified interval. The default value is 900 seconds (15 minutes).

Transmission of messages between the client and the server takes place at a specified time interval.

The QAManager PutMessage() method causes messages to be queued locally. These messages are not transmitted until the time interval has elapsed. Messages queued on the server for delivery to the client are also transmitted when the time interval has elapsed.

If push notifications are enabled, messages queued on the server for delivery to the client are transmitted when the next time interval elapses.

TriggerSendReceive() can override the time interval. It forces a message transmission to occur before the time interval elapses.

The optional *interval* argument is the number of seconds between send/receive operations. For example, the following command schedules the QAnywhere Agent to send/receive messages every 20 minutes:

```
qaagent.exe -policy scheduled[1200]
```

- ◆ **automatic** Transmit messages when one of the events described below occurs.

The QAnywhere agent attempts to keep message queues as current as possible. Any of the following events cause messages queued on the client to be delivered to the server and messages queued on the server to be delivered to the client:

- ◆ Invoking PutMessage().
- ◆ Invoking TriggerSendReceive().
- ◆ A push notification.

For information about notifications, see [“Scenario for messaging with push notifications” on page 9](#).

- ◆ A message status change on the client. For example, a status change occurs when an application retrieves a message from a local queue which causes the message status to change from pending to received.
- ◆ **rules-file** Specifies a client transmission rules file. The transmission rules file can indicate a more complicated set of rules to determine when messages are transmitted.

☞ See [“Client transmission rules” on page 234](#).

#### See also

- ◆ [“Determining when message transmission should occur on the client” on page 36](#)
- ◆ [“Scenario for messaging with push notifications” on page 9](#)

## -push option

### Function

Specifies whether push notifications are enabled.

### Syntax

**qaagent -push mode ...**

*mode* : **none** | **connected** | **disconnected**

### Default

**connected**

### Options

Mode	Description
none	Push notifications are disabled for this agent. The Listener (dblsn) is not started.
connected	Push notifications are enabled for this agent over TCP/IP with persistent connection. The Listener (dblsn) is started by qaagent and attempts to maintain a persistent connection to the MobiLink server. This mode is useful when the client device does not have a public IP address or when the MobiLink server is behind a firewall that does not allow UDP messages out. This is the default.
disconnected	<p>Push notifications are enabled for this agent over UDP without a persistent connection. The Listener (dblsn) is started by qaagent but does not maintain a persistent connection to the MobiLink server. Instead, a UDP listener receives push notifications from MobiLink. This mode is useful in the following scenarios when the client device has a public IP address and is reachable by UDP or SMS:</p> <ul style="list-style-type: none"> <li>◆ The client device is using dial-up networking and connection time charges are an issue.</li> <li>◆ There is light message traffic over QAnywhere. Persistent TCP/IP connections consume network server resources, and so could have an impact on scalability.</li> <li>◆ The client device network coverage is unreliable. You can use the automatic policy to transmit messages when connection is possible. Trying to maintain persistent connections in this environment is not useful and can waste CPU resources.</li> </ul> <p>See “-lp option” on page 154.</p>

### Remarks

If you do not want to use notifications, set this option to none. You then do not have to deploy the *dblsn.exe* executable with your clients.

☞ For a description of QAnywhere without notifications, see “Simple messaging scenario” on page 7.

If you are using UDP, you cannot use push notifications in disconnected mode with ActiveSync due to the limitations of the UDP implementation of ActiveSync.

**See also**

- ◆ [“Using push notifications” on page 41](#)
- ◆ [“-pc option” on page 162](#)
- ◆ [“Running the QAnywhere Agent” on page 35](#)
- ◆ [“Notifications of push notification” on page 53](#)

## -q option

### Function

Starts the QAnywhere Agent in quiet mode with the window minimized in the system tray.

### Syntax

```
qaagent -q ...
```

### Default

None.

### Remarks

When you start the QAnywhere Agent in quiet mode with -q, the main window is minimized to the system tray. In addition, the database server for the message store is started with the -qi option.

### See also

- ◆ [“-qi option” on page 168](#)

## **-qi option**

Starts the QAnywhere Agent in quiet mode with the window completely hidden.

### **Syntax**

**qaagent -qi ...**

### **Default**

None.

### **Remarks**

When you start the QAnywhere Agent in quiet mode, on Windows desktop the main window is minimized to the system tray, and on Windows CE the main window is hidden. In addition, the database server for the message store is started with the **-qi** option.

Quiet mode is useful for some Windows CE applications because it prevents an application from being closed when Windows CE reaches its limit of 32 concurrent processes. Quiet mode allows the QAnywhere Agent to run like a service.

When in **-qi** quiet mode, you can only stop the QAnywhere Agent by typing **qastop**.

### **See also**

- ◆ [“-q option” on page 167](#)

## -si option

### Function

Initializes the database for use as a client message store.

### Syntax

```
qaagent -c "connection-string" -si ...
```

### Default

None. You only use this option once, to initialize the client message store.

### Remarks

Before using this option, you must create a SQL Anywhere database. When you use `-si`, the QAnywhere Agent initializes the database with database objects such as QAnywhere system tables; it then exits immediately.

When you run `-si`, you must specify a connection string with the `-c` option that indicates which database to initialize. The connection string specified in the `-c` option should also specify a user ID with DBA privileges. If you do not specify a user ID and password, the default user DBA with password SQL is used.

The `-si` option creates a database user named `ml_qa_user` and password `qanywhere` for the client message store. The user called `ml_qa_user` has permissions suitable for QAnywhere applications only. If you do not change this database user name and password, then you do not need to specify the `pwd` or `uid` in the `-c` option when you start `qaagent`. If you change either of them, then you must supply the `uid` and/or `pwd` in the `-c` option on the `qaagent` command line.

#### Note

You should change the default passwords. To change them, use the GRANT statement. For more information, see [“Changing a password” \[SQL Anywhere Server - Database Administration\]](#).

The `-si` option does not provide an ID for the client message store. You can assign an ID using the `-id` option when you run `-si` or the next time you run `qaagent`; or, if you do not do that, `qaagent` will by default assign the device name as the ID.

When a message store is created but is not set up with an ID, QAnywhere applications local to the message store can send and receive messages, but cannot exchange messages with remote QAnywhere applications. Once an ID is assigned, remote messaging may also occur.

### See also

- ◆ [“Setting up the client message store” on page 33](#)
- ◆ [“Creating a secure client message store” on page 176](#)

### Examples

The following command connects to a database called `qaclient.db` and initializes it as a QAnywhere client message store. The QAnywhere Agent immediately exits when the initialization is complete.

```
qaagent -si -c "DBF=qaclient.db"
```

## -su option

### Function

Upgrades a client message store to the current version. If you are upgrading from a pre-10.0.0 message store, you must first manually unload and reload the message store.

### Syntax

```
qaagent -su -c "connection-string" ...
```

### Remarks

This option is useful if you want to perform custom actions after the unload/reload and before the qaagent upgrade. Use the `-sur` option if you are upgrading from a pre-10.0.0 message store and you want the Agent to automatically perform the unload/reload step for you.

This operation exits when the upgrade is complete.

This operation cannot be undone.

### See also

- ◆ [“-sur option” on page 171](#)

### Example

To upgrade from a version 9 database, first, unload and reload the database:

```
dbunload -q -c "UID=dba;PWD=sql;DBF=qanywhere.db" -ar
```

Next, run qaagent with the `-su` option:

```
qaagent -q -su -c "UID=dba;PWD=sql;DBF=qanywhere.db"
```

## -sur option

### Function

Upgrades a client message store to the current version.

### Syntax

```
qaagent -sur -c "connection-string" ...
```

### Remarks

Specify the database to upgrade in the connection string. The -sur option automatically unloads the message store, reloads it, and upgrades it.

The unload/reload is necessary to upgrade from a version 9 message store to a version 10 message store. The unload/reload can be done manually along with the -su option. For example, if you need to perform custom actions after the reload and before the upgrade, use the -su option.

This operation exits when the upgrade is complete.

This operation cannot be undone.

### See also

- ◆ [“-su option” on page 170](#)

### Example

The following example unloads and reloads a version 9.0.2 SQL Anywhere database called qanywhere.db, making it useful with QAnywhere version 10.0.0.

```
qaagent -q -sur -c "UID=dba;PWD=sql;DBF=qanywhere.db"
```

## -v option

### Function

Allows you to specify what information is logged to the message log file and displayed in the QAnywhere Agent console. A high level of verbosity may affect performance and should normally be used in the development phase only.

### Syntax

```
qaagent -v levels ...
```

### Default

Minimal verbosity.

### Remarks

The -v option affects the log files and console. You only have a message log if you specify -o or -ot on the qaagent command line.

If you specify -v alone, a small amount of information is logged.

The values of *levels* are as follows. You can use one or more of these options at once; for example, -vlm.

- ◆ **+** Turn on all logging options.
- ◆ **l** Show all MobiLink Listener logging. This causes the MobiLink Listener (dblsn) to start with verbosity level -v3.
  - ☞ For more information, see the -v option in the “[Listener syntax](#)” [*MobiLink - Server-Initiated Synchronization*].
- ◆ **m** Show all dbmlsync logging. This causes the SQL Anywhere synchronization client (dbmlsync) to start with verbosity level -v+.
  - ☞ For more information, see the dbmlsync “[-v option](#)” [*MobiLink - Client Administration*].
- ◆ **n** Show all network status change notifications. the QAnywhere Agent receives these notifications from the Listener utility.
- ◆ **p** Show all message push notifications. The QAnywhere Agent receives these notifications from the Listener utility via the MobiLink server, which includes a MobiLink Notifier.
- ◆ **q** Show the SQL that is used to represent the transmission rules.
- ◆ **s** Show all the message synchronizations that are initialized by QAnywhere Agent.

### See also

- ◆ “[-o option](#)” on page 158
- ◆ “[-ot option](#)” on page 161
- ◆ “[-on option](#)” on page 159
- ◆ “[-os option](#)” on page 160

---

## -x option

### Function

Specify the network protocol and the protocol options for communication with the MobiLink server.

### Syntax

```
qaagent -x protocol [ ( protocol-options;... ) ...
```

*protocol*: **http**, **tcPIP**, **https**, **tls**

*protocol-options*: *keyword=value*

### Remarks

For a complete list of *protocol-options*, see “[MobiLink Client Network Protocol Options](#)” [[MobiLink - Client Administration](#)].

The -x option is required when the MobiLink server is not on the same device as the QAnywhere Agent.

You can specify -x multiple times. This allows you to set up failover to multiple MobiLink servers. When you set up failover, the QAnywhere Agent attempts to connect to the MobiLink servers in the order in which you enter them on the command line.

The QAnywhere Agent also has a Listener that receives notifications from the MobiLink server that messages are available at the server for transmission to the client. This Listener only uses the first MobiLink server that is specified, and does not fail over to others.

CHAPTER 8

# Writing Secure Messaging Applications

## Contents

Creating a secure client message store .....	176
Encrypting the communication stream .....	178
Using password authentication with MobiLink .....	179

### About this chapter

This chapter describes techniques for implementing a secure messaging solution.

## Creating a secure client message store

To secure your client message store, you can:

- ◆ Change the default passwords.

See “[Manage client message store passwords](#)” on page 176.

- ◆ Encrypt the contents of the message store.

See “[Encrypting the client message store](#)” on page 177.

### Example

First, create a SQL Anywhere database with an encryption key:

```
dbinit mystore.db -n -i -s -ek some_phrase
```

The `-i` and `-s` options are optimal for small devices. The `-ek` option specifies the encryption key for strong encryption. The `-n` option initializes the database without a transaction log, because a transaction log is not required for or managed by QAnywhere. See “[Initialization utility \(dbinit\)](#)” [*SQL Anywhere Server - Database Administration*].

Next, initialize the database as a client message store:

```
qaagent -id mystore -si -c "dbf=mystore.db;dbkey=some_phrase"
```

Next, create a new remote user with DBA authority, and a password for this user. Revoke the default QAnywhere user and change the password of the default DBA user. Log in as user DBA with password SQL and execute the following SQL statements:

```
GRANT CONNECT TO secure_user IDENTIFIED BY secure_password
GRANT MEMBERSHIP IN GROUP ml_qa_user_group TO secure_user
GRANT REMOTE dba TO secure_user
REVOKE CONNECT FROM ml_qa_user
GRANT CONNECT TO dba IDENTIFIED BY new_dba_password
COMMIT
```

#### Note

All QAnywhere users must belong to `ml_qa_user_group` and have remote DBA authority.

Next, start the QAnywhere Agent with the secure DBA user:

```
qaagent -id mystore -c
"dbf=mystore.db;dbkey=some_phrase;uid=secure_user;pwd=secure_password"
```

## Manage client message store passwords

You should change the passwords for the default user IDs that were created for the message store. The default user ID DBA with password SQL is created for every SQL Anywhere database. In addition, the `qaagent -si`

option creates a default user ID of ml\_qa\_user, and creates a default password of qanywhere. To change these passwords, use the GRANT statement.

☞ For more information, see “Changing a password” [[SQL Anywhere Server - Database Administration](#)].

## Encrypting the client message store

The following command can be used to encrypt the client message store when you create it.

```
dbinit -n -i -s -ek encryption-key database-file
```

(The -i and -s options are good practice for creating databases on small devices.) When a message store has been initialized with an encryption key, the encryption key is required to start the database server on the encrypted message store.

Use the following command to specify the encryption key to start the QAnywhere Agent with an encrypted message store. The QAnywhere Agent automatically starts the database server on the encrypted message store using the encryption key provided.

```
qaagent -c "DBF=database-file;DBKEY=encryption-key"
```

Any application can now access the encrypted message store through the QAnywhere APIs. Note that, since the database server used to manage the message store is already running, the application does not need to provide the encryption key.

If the QAnywhere Agent is not running and an application needs to access an encrypted message store, the QAnywhere APIs automatically starts the database server using the connection parameters specified in the QAnywhere Manager initialization file. In order to start the database server on an encrypted message store, the encryption key must be specified in the database connection parameters as follows.

```
CONNECT_PARAMS=DBF=database-file;DBKEY=encryption-key
```

### See also

- ◆ “Encrypting a database” [[SQL Anywhere Server - Database Administration](#)]
- ◆ “Initialization utility (dbinit)” [[SQL Anywhere Server - Database Administration](#)]
- ◆ QAnywhere Agent “-c option” on page 148

## Encrypting the communication stream

The `qaagent -x` option can be used to specify a secure communication stream that the QAnywhere Agent can use to communicate with a MobiLink server. It allows you to implement server authentication using server-side certificates, and it allows you to encrypt the communication stream using strong encryption.

☞ For more information, see “[-x option](#)” on page 173.

You must set up transport-layer security for the MobiLink server as well. For information about creating digital certificates and setting up the MobiLink server, see “[Encrypting MobiLink client/server communications](#)” [*SQL Anywhere Server - Database Administration*].

### Separately licensed component required

ECC encryption and FIPS-approved encryption require a separate license. All strong encryption technologies are subject to export regulations.

See “[Separately licensed components](#)” [*SQL Anywhere 10 - Introduction*].

### Examples

The following examples show how to establish a secure communication stream between the QAnywhere Agent and the MobiLink server. They use sample certificates that are installed when the SQL Anywhere security option is installed.

Secure TCP/IP using RSA:

```
mlsrv10 -x tls
(tls_type=rsa;certificate=rsaserver.crt;certificate_password=test)
qaagent -x tls(tls_type=rsa;trusted_certificates=rsaroot.crt)
```

Secure TCP/IP using ECC:

```
mlsrv10 -x tls
(tls_type=ecc;certificate=sample.crt;certificate_password=tJl#m6+W)
qaagent -x tls(tls_type=ecc;trusted_certificates=eccroot.crt)
```

Secure HTTP using HTTPS (only RSA certificates are supported for HTTPS):

```
mlsrv10 -x https(certificate=rsaserver.crt;certificate_password=test)
qaagent -x https(trusted_certificates=rsaroot.crt)
```

## Using password authentication with MobiLink

Once you have established a secure communication stream between the remote device and the server, you may also want to authenticate the user of the device to ensure that they are allowed to communicate with the server.

You do this by creating a MobiLink user name for the client message store and registering it on the server message store.

Compiling and running mobile web service applications .....	191
Making web service requests .....	192
Setting up web service connectors .....	195
Mobile web service example .....	198

### About this chapter

QAnywhere provides functionality that greatly simplifies the development of mobile web service applications. This functionality is provided in the Java and .NET APIs.

This chapter describes how to write QAnywhere client applications that access a web service.

## Introducing mobile web services

Web Services have become a popular way to expose application functionality and enable better interoperability between the resources of various enterprises. They broaden the capabilities of mobile applications and simplify the development process.

Implementing web services in a mobile environment can be challenging because connectivity may not be available (or may be interrupted) and because of other limitations of wireless environments and devices. For example, a user working with a mobile application may want to make a request to a web service while offline and obtain the response when they go online, or an IT administrator may want to specify rules that restrict the size of web service responses based on the type of network connectivity the mobile application is using (such as GPRS, 802.11, or cradled).

QAnywhere addresses these challenges with mobile-optimized asynchronous web services that leverage the QAnywhere store-and-forward messaging architecture. By using QAnywhere mobile web services, your mobile applications can make web service requests, even when they are offline, and have those requests queued up for transmission later. The requests are delivered as QAnywhere messages and then a web services connector on the server side makes the request, gets the response from the web service, and returns the response to the client as a message. QAnywhere transmission rules can control which requests and responses are transmitted based on a wide variety of parameters (network being used, size of request/response, location, time of day, and so on). The result is a sophisticated and flexible architecture that allows mobile applications to tap into the vast functionality of web services using proven technology and a simple programming model.

From a development point of view, you can work with web service proxy classes much as you would in a connected environment and QAnywhere handles all of the transmission, authentication, serialization, and so on. A WSDL compiler is provided to take a WSDL document and generate special proxy classes (either .NET or Java) that a mobile application can use to invoke a web service. These classes use the underlying QAnywhere infrastructure to send requests and receive responses. When an object method call is made, a SOAP request is built automatically and delivered as a message to the server where a connector makes the web service request and returns the result as a message.

## Setting up mobile web services

The following steps provide an overview of the tasks required to set up mobile web services.

### ◆ Overview of setting up mobile web services

1. Set up a server message store, if you don't already have one.
  - ☞ See [“Setting up the server message store” on page 30](#).
2. Start the MobiLink server with the -m option and a connection to the server message store.
  - ☞ See [“Starting the MobiLink server for QAnywhere messaging” on page 31](#).

3. Set up client message stores, if you don't already have them. These are SQL Anywhere databases that are used to temporarily store messages.
  - ☞ See [“Setting up the client message store” on page 33](#).
4. Run the QAnywhere WSDL compiler to create classes you can use in your application.
  - ☞ See [“Running the QAnywhere WSDL compiler” on page 184](#).
5. For each client, write a web service client application that uses the classes generated by the WSDL compiler.
  - ☞ See [“Writing mobile web service applications” on page 185](#).
6. Create a web services connector.
  - ☞ See [“Setting up web service connectors” on page 195](#).
7. For each client, start the QAnywhere Agent (qaagent) with a connection to the local client message store.
  - ☞ See [“Running the QAnywhere Agent” on page 35](#).

#### **Other resources for getting started**

- ◆ A simple example using a hypothetical web service is described in [“Mobile web service example” on page 198](#).
- ◆ A full-featured mobile web service sample application is installed to `samples-dir\QAnywhere\MobileWebServices`. (For information about `samples-dir`, see [“The samples directory” \[SQL Anywhere Server - Database Administration\]](#).) This sample, which is provided in both Java and C#, demonstrates how to use mobile web services to make asynchronous web service requests.

## Running the QAnywhere WSDL compiler

Given a WSDL file that describes a web service, the QAnywhere WSDL compiler generates a set of Java or C# proxy classes that you include in your application. These classes expose web service operations as method calls. The classes that are generated are:

- ◆ The main service binding class (this class inherits from WSBBase in the mobile web services runtime).
- ◆ A proxy class for each complex type specified in the WSDL file.

For information about the generated proxy classes, see:

- ◆ .NET: [“iAnywhere.QAnywhere.WS namespace \(.NET \)” on page 342](#)
- ◆ Java: [“ianywhere.qanywhere.ws package” on page 602](#)

The WSDL compiler supports WSDL 1.1 and SOAP 1.1 over HTTP and HTTPS.

### Syntax

`wsdlc -l programming-language wsdl-file [ options ]`

### Parameters

*programming-language*: **cs** | **java**

*wsdl-file*: the name of the WSDL file that describes a web service

Options	Description
-h	Print a help screen.
-v	Print verbose information.
-o <i>output-directory</i>	Specify an output directory for generated files.
-d	Print debug information.
-n	For C# output only, specify a namespace.
-p	For Java output only, specify a package name.

## Writing mobile web service applications

Your application sends a web service request to QAnywhere, which sends the request to the mobile web service connector in the MobiLink server. The connector sends the request to the web service or queues the request until the web service is available. When QAnywhere receives the response, it notifies your application or queues the response until your application is available.

### Setting up .NET mobile web service applications

Before using .NET with QAnywhere, you must make the following changes to your Visual Studio .NET project:

- ◆ Add references to the QAnywhere .NET DLL and the mobile web services .NET DLL. This tells Visual Studio.NET which DLL to include to find the code for the QAnywhere .NET API and the mobile web services .NET API.
- ◆ Add lines to your source code to reference the QAnywhere .NET API classes and the mobile web services .NET API classes. In order to use the QAnywhere .NET API, you must add a line to your source code to reference the data provider. You must add a different line for C# than for Visual Basic.NET.

Complete instructions follow.

#### ◆ To add references to the QAnywhere .NET API and mobile web services API in a Visual Studio .NET project

1. Start Visual Studio .NET and open your project.
2. In the Solution Explorer window, right-click the References folder and choose Add Reference from the popup menu.

The Add Reference dialog appears.

3. On the .NET tab, click Browse to locate *iAnywhere.QAnywhere.Client.dll* and *iAnywhere.QAnywhere.WS.dll*. The location of these files is (relative to your SQL Anywhere installation directory):

- ◆ .NET Framework 1.1: `\Assembly\v1`
- ◆ .NET Framework 2.0: `\Assembly\v2`
- ◆ .NET Compact Framework 1.0: `ce\Assembly\v1`
- ◆ .NET Compact Framework 2.0: `ce\Assembly\v2`

From the appropriate directory for your environment, select each DLL and click Open.

4. To verify that the DLLs are added to your project, open the Add Reference dialog and open the .NET tab. *iAnywhere.QAnywhere.Client.dll* and *iAnywhere.QAnywhere.WS.dll* appear in the Selected Components list. Click OK.

## Referencing the data provider classes in your source code

### ◆ To reference the QAnywhere .NET API and mobile web services API classes in your code

1. Start Visual Studio .NET and open your project.
2. If you are using C#, add the following lines to the list of using directives at the beginning of your file:

```
using iAnywhere.QAnywhere.Client;  
using iAnywhere.QAnywhere.WS;
```

3. If you are using Visual Basic .NET, add the following lines to the list of imports at the beginning of your file:

```
Imports iAnywhere.QAnywhere.Client  
Imports iAnywhere.QAnywhere.WS
```

The Imports lines are not strictly required. However, they allow you to use short forms for the QAnywhere and mobile web services classes. Without them, you can still use the fully qualified class name in your code. For example, the following code uses the long form:

```
iAnywhere.QAnywhere.Client.QAManager  
mgr =  
    new iAnywhere.QAnywhere.Client.QAManagerFactory.Instance.CreateQAManager  
    (  
        "qa_manager.props" );
```

The following code uses the short forms:

```
QAManager mgr = QAManagerFactory.Instance.CreateQAManager(  
    "qa_manager.props" );
```

### ◆ To initialize QAnywhere and mobile web services for .NET

1. Include the iAnywhere.QAnywhere.Client and iAnywhere.QAnywhere.WS namespaces, as described in the previous procedure.

```
using iAnywhere.QAnywhere.Client;  
using iAnywhere.QAnywhere.WS;
```

2. Create a QAManager object.

For example, to create a default QAManager object, invoke CreateQAManager with null as its parameter:

```
QAManager mgr;  
mgr = QAManagerFactory.Instance.CreateQAManager( null );
```

#### Tip

For maximum concurrency benefits, multi-threaded applications should create a QAManager for each thread. See [“Multi-threaded QAManager” on page 61](#).

☞ For more information about QAManagerFactory, see [“QAManagerFactory class” on page 310](#).

Alternatively, you can create a QAManager object that is customized using a properties file. The properties file is specified in the CreateQAManager method:

```
mgr = QAManagerFactory.Instance.CreateQAManager(
    "qa_mgr.props" );
```

where *qa\_mgr.props* is the name of the properties file that resides on the remote device.

3. Initialize the QAManager object. For example:

```
mgr.Open(
    AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT);
```

The argument to the open method is an acknowledgement mode, which indicates how messages are to be acknowledged. It must be one of `IMPLICIT_ACKNOWLEDGEMENT` or `EXPLICIT_ACKNOWLEDGEMENT`.

QAnywhere messages used by mobile web services are not accessible to the mobile web services application. When using a QAManager in `EXPLICIT_ACKNOWLEDGEMENT` mode, use the `Acknowledge` method of `WSResult` to acknowledge the QAnywhere message that contains the result of a web services request. This method indicates that the application has successfully processed the response.

For more information about acknowledgement modes, see:

- ◆ WSBBase “[SetQAManager method](#)” on page 346
- ◆ WSResult “[Acknowledge method](#)” on page 358

Instead of creating a QAManager, you can create a QATransactionalManager. See “[Implementing transactional messaging for .NET clients](#)” on page 68.

4. Create an instance of the service binding class.

The mobile web services WSDL compiler generates the service binding class from the WSDL document that defines the web service.

The QAManager is used by the instance of the web service binding class to perform messaging operations in the process of making web service requests. You specify the connector address to use to send web service requests through QAnywhere by setting the property `WS_CONNECTOR_ADDRESS` of the service binding class. You configure each QAnywhere web service connector with the URL of a web service to connect to, and if an application needs web services located at more than one URL, configure the connector for each URL.

For example:

```
CurrencyConverterSoap service = new CurrencyConverterSoap( )
service.SetQAManager(mgr);
service.setProperty(
    "WS_CONNECTOR_ADDRESS",
    "iAnywhere.connector.currencyconvortor\\");
```

Note that the final `\\` in the address must be included.

#### See also

- ◆ “[iAnywhere.QAnywhere.WS namespace \(.NET\)](#)” on page 342

- ◆ [“iAnywhere.QAnywhere.Client namespace \(.NET\)” on page 244](#)

### Example

To initialize mobile web services, you must create a QAManager and create an instance of the service binding class. For example:

```
// QAnywhere initialization
    QAManager mgr = QAManagerFactory.Instance.CreateQAManager( null );
    mgr.SetProperty( "CONNECT_PARAMS",
"eng=qanywhere;dbf=qanywhere.db;uid=ml_qa_user;pwd=qanywhere" );
    mgr.Open( AcknowledgementMode.IMPLICIT_ACKNOWLEDGEMENT );
    mgr.Start();

    // Instantiate the web service proxy
    CurrencyConvertorSoap service = new CurrencyConvertorSoap();
    service.SetQAManager( mgr );
    service.SetProperty( "WS_CONNECTOR_ADDRESS",
"ianywhere.connector.currencyconvertor\\" );
```

## Setting up Java mobile web service applications

To create mobile web service applications in Java, you must complete the following initialization tasks.

### ◆ To initialize QAnywhere and mobile web services for Java

1. Add the location of the following files to your classpath. By default, they are located in *install-dir* \java:

- ◆ *qaclient.jar*
- ◆ *iawsrt.jar*
- ◆ *jaxrpc.jar*

2. Import the *ianywhere.qanywhere.client* and *ianywhere.qanywhere.ws* packages:

```
import ianywhere.qanywhere.client.*;
import ianywhere.qanywhere.ws.*;
```

3. Create a QAManager object.

```
QAManager mgr;
mgr = QAManagerFactory.getInstance().createQAManager(null);
```

You can also customize a QAManager object by specifying a properties file to the *createQAManager* method:

```
mgr = QAManagerFactory.getInstance().createQAManager("qa_mgr.props.");
```

#### Tip

For maximum concurrency benefits, multi-threaded applications should create a QAManager for each thread. See [“Multi-threaded QAManager” on page 61](#).

4. Initialize the QAManager object.

```
mgr.open(AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT);
```

The argument to the open method is an acknowledgement mode, which indicates how messages are to be acknowledged. It must be one of `IMPLICIT_ACKNOWLEDGEMENT` or `EXPLICIT_ACKNOWLEDGEMENT`.

QAnywhere messages used by mobile web services are not accessible to the mobile web services application. When using a `QAManager` in `EXPLICIT_ACKNOWLEDGEMENT` mode, use the `Acknowledge` method of `WSResult` to acknowledge the QAnywhere message that contains the result of a web services request. This method indicates that the application has successfully processed the response.

For more information about acknowledgement modes, see:

- ◆ [WSBase “setQAManager method” on page 605](#)
- ◆ [WSResult “acknowledge method” on page 611](#)

Instead of creating a `QAManager`, you can create a `QATransactionalManager`. See [“Implementing transactional messaging for Java clients” on page 71](#).

#### 5. Create an instance of the service binding class.

The mobile web services WSDL compiler generates the service binding class from the WSDL document that defines the web service.

In the process of making web service requests, the `QAManager` is used by the instance of the web service binding class to perform messaging operations. You specify the connector address to use to send web service requests through QAnywhere by setting the `WS_CONNECTOR_ADDRESS` property of the service binding class. Each QAnywhere web service connector is configured with a URL of a web service to connect to. This means that if an application needs web services located at more than one URL, then a QAnywhere connector must be configured for each service URL.

For example:

```
CurrencyConverterSoap service = new CurrencyConverterSoap( );
service.setQAManager(mgr);
service.setProperty("WS_CONNECTOR_ADDRESS",
"iAnywhere.connector.currencyconvertor\\");
```

Note that the final `\\` in the address must be included.

#### See also

- ◆ [“iAnywhere.qanywhere.ws package” on page 602](#)
- ◆ [“iAnywhere.qanywhere.client package” on page 504](#)

#### Example

To initialize mobile web services, you must create a `QAManager` and create an instance of the service binding class. For example:

```
// QAnywhere initialization
Properties props = new Properties();
props.put("CONNECT_PARAMS",
"eng=qanywhere;dbf=qanywhere.db;uid=ml_qa_user;pwd=qanywhere");
```

```
QAManager mgr = QAManagerFactory.getInstance().createQAManager( props );
mgr.open( AcknowledgementMode.IMPLICIT_ACKNOWLEDGEMENT );
mgr.start();

// Instantiate the web service proxy
CurrencyConvertorSoap service = new CurrencyConvertorSoap();
service.setQAManager( mgr );
service.setProperty( "WS_CONNECTOR_ADDRESS",
"ianywhere.connector.currencyconvertor\\" );
```

### Multiple instances of the service binding class

You should create an instance of the service binding class for each QAManager. If a mobile web services application has more than one instance of a service binding class, it is important that the service ID be set using the SetServiceID method. For example:

```
service1.SetServiceID( "1" )
service2.SetServiceID( "2" )
```

The service ID is combined with the service name to form a queue name for receiving web service responses. It is important that each instance of a given service has a unique service ID so that a given instance does not get responses to requests made by another instance of the service. If the service ID is not set, it defaults to "". The service ID is also important for preventing multiple applications that use the same service from conflicting with each other, since queue names persist messages in the message store across applications that are transient.

# Compiling and running mobile web service applications

## Runtime libraries

The runtime library for Java is *iawsrt.jar*, located in the *java* subdirectory of your SQL Anywhere installation.

The runtime library for C# is *iAnywhere.QAnywhere.WS.dll*, located in the following directories (relative to your SQL Anywhere directory):

- ◆ .NET Framework 1.1: *\Assembly\v1*
- ◆ .NET Framework 2.0: *\Assembly\v2*
- ◆ .NET Compact Framework 1.0: *ce\Assembly\v1*
- ◆ .NET Compact Framework 2.0: *ce\Assembly\v2*

The following sections describe the files you need to compile and run mobile web service applications.

## Required runtime libraries (Java)

Include the following files, located in the *java* subdirectory of your SQL Anywhere 10 installation, in your classpath:

- ◆ *jaxrpc.jar*
- ◆ *qaclient.jar*
- ◆ *iawsrt.jar*

## Required runtime libraries (.NET)

The SQL Anywhere 10 installation automatically includes the following files in your Global Assembly Cache:

- ◆ *iAnywhere.QAnywhere.Client.dll*
- ◆ *iAnywhere.QAnywhere.WS.dll*

## Shutting down mobile web services

A mobile web services application performs orderly shutdown by closing the QAManager. For example:

```
// QAnywhere finalization in C#:  
mgr.Stop();  
mgr.Close();  
  
// QAnywhere finalization in Java:  
mgr.stop();  
mgr.close();
```

## Making web service requests

There are two basic methods of making web service requests in a mobile web services application:

- ◆ **Synchronous** See [“Synchronous web service requests” on page 192.](#)
- ◆ **Asynchronous** See [“Asynchronous web service requests” on page 192.](#)

### Synchronous web service requests

Synchronous web service requests are used when the application is connected to a network. With this method, a web service request is made by calling a method on the service binding class, and the result is returned only when the web service response has been received from the server.

#### Example

The following example makes a request to get the USD-to-CAD exchange rate:

```
//C#
double r = service.ConversionRate( Currency.USD, Currency.CAD );

// Java
double r = service.conversionRate( NET.webserviceX.Currency.USD,
NET.webserviceX.Currency.CAD );
```

### Asynchronous web service requests

Asynchronous web service requests are useful when the mobile web service application is only occasionally connected to a network. With this method, a web service request is made by calling a method on the service binding class to place the request in an outgoing queue. The method returns a `WSResult`, which can be used to query the status of the response at a later time, even after the application has been restarted.

The following example makes an asynchronous request to get the USD-to-CAD exchange rate:

```
// C#
WSResult r = service.AsyncConversionRate( Currency.USD, Currency.CAD );

// Get the request ID. Save it for later use if necessary.
string reqID = r.GetRequestID();

// Later: get the response for the specified request ID
WSResult r = service.GetResult( reqID );
if( r.GetStatus() == WSStatus.STATUS_RESULT_AVAILABLE ) {
    Console.WriteLine( "The conversion rate is " + r.GetDoubleValue
( "ConversionRateResult" ) );
} else {
    Console.WriteLine( "Response not available" );
}

// Java
WSResult r = service.asyncConversionRate( NET.webserviceX.Currency.USD,
NET.webserviceX.Currency.CAD );

// Get the request ID. Save it for later use if necessary.
```

```
String reqID = r.getRequestID();

// Later: get the response for the specified request ID
WSResult r = service.getResult( reqID );
if( r.getStatus() == WSStatus.STATUS_RESULT_AVAILABLE ) {
    System.out.println( "The conversion rate is " + r.getDoubleValue
( "ConversionRateResult" ) );
} else {
    System.out.println( "Response not available" );
}
}
```

It is also possible to use a `WSListener` to get an asynchronous callback when the response to a web service request is available. For example:

```
// C#
// Make a request to get the USD to CAD exchange rate
WSResult r = service.AsyncConversionRate( Currency.USD, Currency.CAD );

// Register a listener for the result
service.SetListener( r.GetRequestID(), new CurrencyConvertorListener() );

// Java
// Make a request to get the USD to CAD exchange rate
WSResult r = service.asyncConversionRate( NET.webserviceX.Currency.USD,
NET.webserviceX.Currency.CAD );

// Register a listener for the result
service.setListener( r.getRequestID(), new CurrencyConvertorListener() );
```

The `WSListener` interface defines two methods for handling asynchronous events:

- ◆ **OnResult** An `OnResult` method is implemented to handle a response to a web service request. It is passed a `WSResult` object that represents the result of the web service request.
- ◆ **OnException** An `OnException` method is implemented to handle errors that occurred during processing of the response to the web service request. It is passed a `WSEException` object and a `WSResult` object. The `WSEException` object contains information about the error that occurred, and the `WSResult` object can be used to obtain the request ID that the response corresponds to.

```
// C#
class CurrencyConvertorListener : WSListener
{
    public CurrencyConvertorListener() {
    }

    public void OnResult( WSResult r ) {
        try {
            USDToCAD._statusMessage = "USD to CAD currency exchange rate: " +
r.GetDoubleValue( "ConversionRateResult" );
        } catch( Exception exc ) {
            USDToCAD._statusMessage = "Request " + r.GetRequestID() + " failed: "
+ exc.Message;
        }
    }

    public void OnException( WSEException exc, WSResult r ) {
        USDToCAD._statusMessage = "Request " + r.GetRequestID() + " failed: " +
exc.Message;
    }
}
```

```
// Java
private class CurrencyConvertorListener implements WSListener
{
    public CurrencyConvertorListener() {
    }

    public void onResult( WSResult r ) {
        try {
            USDToCAD._statusMessage = "USD to CAD currency exchange rate: " +
r.getDoubleValue( "ConversionRateResult" );
        } catch( Exception exc ) {
            USDToCAD._statusMessage = "Request " + r.getRequestID() + " failed: "
+ exc.getMessage();
        }
    }

    public void onException( WSExcption exc, WSResult r ) {
        USDToCAD._statusMessage = "Request " + r.getRequestID() + " failed: "
+ exc.getMessage();
    }
}
```

## Setting up web service connectors

A web service connector listens for QAnywhere messages sent to a particular address, and makes web service calls when messages arrive. Web service responses are sent back to the originating client as QAnywhere messages. All messages sent to the web services connector should be created using the proxy classes generated by the QAnywhere WSDL compiler.

### ◆ To create a web service connector

1. Open Sybase Central and connect to your server message store.

2. Choose File ► New Connector.

The Connector wizard appears.

3. In the Connector Type page, choose Web Services and click Next.

4. In the Connector Name page, enter the Connector Name.

This is the connector address that a QAnywhere client should use to address the connector. It sets the property `ianywhere.connector.address`.

5. In the Communication Parameters page, enter the URL.

This is the URL where the web service is located. (For example, *http://localhost:8080/qanyserv/F2C*.) It sets the property `webservice.url`.

You can optionally specify a timeout period in milliseconds, which cancels requests if the web service does not respond in the amount of time you specify. This sets the property `webservice.socket.timeout`.

6. In the HTTP Parameters page, optionally enter the following values:

- ◆ **HTTP User Name** If the web service requires HTTP authentication, use this property to specify the user name.

This sets the property `webservice.http.authName`.

- ◆ **HTTP Password** If the web service requires HTTP authentication, use this property to specify the password.

This sets the property `webservice.http.password.e`.

- ◆ **Proxy Host Name** If the web service must be accessed through an HTTP proxy, use this property to specify the host name. If you specify this property, you must specify the `webservice.http.proxy.port` property.

This sets the property `webservice.http.proxy.host`.

- ◆ **Proxy Port** The port to connect to on the proxy server. If you specify this property, you must specify the `webservice.http.proxy.host` property.

This sets the property `webservice.http.proxy.port`.

- ◆ **Proxy User Name** The proxy user name to use if the proxy requires authentication. If you specify this property, you must also specify the `webservice.http.proxy.password.e` property.

This sets the property `webservice.http.proxy.authName`.

- ◆ **Proxy Password** The proxy password to use if the proxy requires authentication. If you specify this property, you must also specify the `webservice.http.proxy.authName` property.

This sets the property `webservice.http.proxy.password.e`.

7. Click Finish.
8. To set additional options on your web service connector, you can right-click the connector you just created and choose Properties; or you can use server management requests.

☞ For a list of available properties, see [“Web service connector properties” on page 196](#).

☞ For information about using server management requests, see [“Administering connectors” on page 104](#).

## Web service connector properties

Use web service connector properties to specify connection information with the web service. You can set these properties in the Sybase Central Connector wizard.

☞ See [“Setting up web service connectors” on page 195](#).

You can view web service connector properties in the Sybase Central Connector Properties dialog, or in the `ml_qa_global_props` MobiLink system table.

To open the Connector Properties dialog, right-click the connector in Sybase Central and choose Properties.

☞ For more information about the `ml_qa_global_props` MobiLink system table, see [“ml\\_qa\\_global\\_props” \[MobiLink - Server Administration\]](#).

## Web service connector properties

- ◆ **ianywhere.connector.nativeConnection** The Java class that implements the connector. It is for QAnywhere internal use only, and should not be deleted or modified.
- ◆ **ianywhere.connector.id (deprecated)** An identifier that uniquely identifies the connector. The default is `ianywhere.connector.address`.
- ◆ **ianywhere.connector.address** The connector address that a QAnywhere client should use to address the connector. This address is also used to prefix all logged error, warning, and informational messages appearing in the server console for this connector.

In Sybase Central, you set this property in the Connector wizard, Connector Name page, Connector Name field.

- ◆ **ianywhere.connector.compressionLevel** The default compression factor of messages received from the web service. Compression is an integer between 0 and 9, with 0 indicating no compression and 9 indicating maximum compression.

In Sybase Central, you set this property on the connector properties dialog, on the General tab, in the Compression Level section.

- ◆ **ianywhere.connector.logLevel** The amount of connector information displayed in the MobiLink server console and log file. Values for the log level are as follows:

- ◆ **1** Log error messages.
- ◆ **2** Log error and warning messages.
- ◆ **3** Log error, warning, and information messages.
- ◆ **4** Log error, warning, information, and debug messages.

In Sybase Central, you set this property on the connector properties dialog, on the General tab, in the Logging Level section.

- ◆ **ianywhere.connector.outgoing.retry.max** The default number of retries for messages going from QAnywhere to the external messaging system. The default value is 5. Specify 0 to have the connector retry forever.

In Sybase Central, you can set this property in the connector properties dialog Properties tab, by clicking New.

- ◆ **ianywhere.connector.startupType** Startup types can be automatic, manual, or disabled.
- ◆ **webservice.http.authName** If the web service requires HTTP authentication, use this property to specify the user name.
- ◆ **webservice.http.password.e** If the web service requires HTTP authentication, use this property to specify the password.
- ◆ **webservice.http.proxy.authName** If the proxy requires authentication, use this property to set the proxy user name. If you specify this property, you must also specify the `webservice.http.proxy.password.e` property.
- ◆ **webservice.http.proxy.host** If the web service must be accessed through an HTTP proxy, use this property to specify the host name. If you specify this property, you must specify the `webservice.http.proxy.port` property.
- ◆ **webservice.http.proxy.password.e** If the proxy requires authentication, use this property to set the proxy password. If you specify this property, you must also specify the `webservice.http.proxy.authName` property.
- ◆ **webservice.http.proxy.port** The port to connect to on the proxy server. If you specify this property, you must specify the `webservice.http.proxy.host` property.

## Mobile web service example

This example shows you how to create a mobile web service application. The example uses a non-existent web service and so is designed to be read, not run.

For a more full-featured example, see the sample that is installed to *samples-dir\QAnywhere\MobileWebServices*. (For information about *samples-dir*, see [“The samples directory” \[SQL Anywhere Server - Database Administration\]](#).)

### Global Weather web service

Suppose there is a web service called Global Weather. The following WSDL file, called *globalweather.wsdl*, describes this web service:

```
<?xml version="1.0" encoding="utf-8"?>
<wsdl:definitions xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:s="http://www.w3.org/2001/XMLSchema"
  xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
  xmlns:tns="http://www.myweather.com"
  targetNamespace="http://www.myweather.com"
  xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/" >

  <wsdl:types>
    <s:schema targetNamespace="http://www.myweather.com">
      <s:element name="GetWeather">
        <s:complexType>
          <s:sequence>
            <s:element minOccurs="0" maxOccurs="1" name="CityName"
type="s:string" />
            <s:element minOccurs="0" maxOccurs="1" name="CountryName"
type="s:string" />
          </s:sequence>
        </s:complexType>
      </s:element>
      <s:element name="GetWeatherResponse">
        <s:complexType>
          <s:sequence>
            <s:element minOccurs="0" maxOccurs="1" name="GetWeatherResult"
type="s:string" />
          </s:sequence>
        </s:complexType>
      </s:element>
    </s:schema>
  </wsdl:types>

  <wsdl:message name="GetWeatherSoapIn">
    <wsdl:part name="parameters" element="tns:GetWeather" />
  </wsdl:message>
  <wsdl:message name="GetWeatherSoapOut">
    <wsdl:part name="parameters" element="tns:GetWeatherResponse" />
  </wsdl:message>

  <wsdl:portType name="GlobalWeatherSoap">
    <wsdl:operation name="GetWeather">
      <wsdl:input message="tns:GetWeatherSoapIn" />
      <wsdl:output message="tns:GetWeatherSoapOut" />
    </wsdl:operation>
  </wsdl:portType>
```

```

    <wsdl:binding name="GlobalWeatherSoap" type="tns:GlobalWeatherSoap">
      <soap:binding transport="http://schemas.xmlsoap.org/soap/http"
style="document" />
      <wsdl:operation name="GetWeather">
        <soap:operation soapAction="http://www.myweather.com/GetWeather"
style="document" />
        <wsdl:input>
          <soap:body use="literal" />
        </wsdl:input>
        <wsdl:output>
          <soap:body use="literal" />
        </wsdl:output>
      </wsdl:operation>
    </wsdl:binding>

    <wsdl:service name="GlobalWeather">
      <wsdl:port name="GlobalWeatherSoap" binding="tns:GlobalWeatherSoap">
        <soap:address location="http://www.myweather.com/" />
      </wsdl:port>
    </wsdl:service>

  </wsdl:definitions>

```

### Generate proxy class

To create a mobile application to access the Global Weather web service, you first run the QAnywhere WSDL compiler. It generates a proxy class that can be used in an application to make requests of the global weather service. In this example, the application is written in Java.

```
wsdlc -l java globalweather.wsdl
```

This command generates a proxy class called *GlobalWeatherSoap.java*, located in the *com\myweather* directory (relative to the current directory). This proxy class is the service binding class for your application. The following is the content of *GlobalWeatherSoap.java*:

```

/*
 * GlobalWeatherSoap.java
 *
 * Generated by the iAnywhere WSDL Compiler
 */

package com.myweather;

import ianywhere.qanywhere.ws.*;
import ianywhere.qanywhere.client.QABinaryMessage;
import ianywhere.qanywhere.client.QAException;

public class GlobalWeatherSoap extends ianywhere.qanywhere.ws.WSBase
{
    public GlobalWeatherSoap(String iniFile) throws WSException
    {
        super(iniFile);
        init();
    }

    public GlobalWeatherSoap() throws WSException
    {
        init();
    }
}

```

```

public void init()
{
    setServiceName("GlobalWeather");
}

public java.lang.String getWeather(java.lang.String cityName,
    java.lang.String countryName) throws
    QAEException,WSEException,WSFaultException
{
    StringBuffer    soapRequest = new StringBuffer();
    QABinaryMessage qaRequestMsg = null;
    String          responsePartName = "GetWeatherResult";
    java.lang.String    returnValue;

    writeSOAPHeader( soapRequest, "GetWeather", "http://
www.myweather.com" );
    soapRequest.append( WSBASETypeSerializer.serialize
("CityName",cityName,"string","http://www.w3.org/2001/
XMLSchema",true,true) );
    soapRequest.append( WSBASETypeSerializer.serialize
("CountryName",countryName,"string","http://www.w3.org/2001/
XMLSchema",true,true) );
    writeSOAPFooter( soapRequest, "GetWeather" );

    qaRequestMsg = createQAMessage( soapRequest.toString(), "http://
www.myweather.com/GetWeather", "GetWeatherResponse" );

    WSResult wsResult = invokeWait( qaRequestMsg );

    returnValue = wsResult.getStringValue(responsePartName);

    return returnValue;
}

public WSResult asyncGetWeather(java.lang.String cityName,
    java.lang.String countryName) throws
    QAEException,WSEException
{
    StringBuffer    soapRequest = new StringBuffer();
    QABinaryMessage qaRequestMsg = null;

    writeSOAPHeader( soapRequest, "GetWeather", "http://
www.myweather.com" );
    soapRequest.append( WSBASETypeSerializer.serialize
("CityName",cityName,"string","http://www.w3.org/2001/
XMLSchema",true,true) );
    soapRequest.append( WSBASETypeSerializer.serialize
("CountryName",countryName,"string","http://www.w3.org/2001/
XMLSchema",true,true) );
    writeSOAPFooter( soapRequest, "GetWeather" );

    qaRequestMsg = createQAMessage( soapRequest.toString(), "http://
www.myweather.com/GetWeather", "GetWeatherResponse" );

    WSResult wsResult = invoke( qaRequestMsg );

    return wsResult;
}
}

```

## Write mobile web service applications

Next, write applications that use the service binding class to make requests of the web service and process the results. Following are two applications, both of which make web service requests offline and process the results at a later time.

The first application, called RequestWeather, makes a request of the global weather service and displays the ID of the request:

```
import ianywhere.qanywhere.client.*;
import ianywhere.qanywhere.ws.*;
import com.myweather.GlobalWeatherSoap;

class RequestWeather
{
    public static void main( String [] args ) {
        try {
            // QAnywhere initialization
            QAManager mgr = QAManagerFactory.getInstance().createQAManager();
            mgr.open( AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT );
            mgr.start();

            // Instantiate the web service proxy
            GlobalWeatherSoap service = new GlobalWeatherSoap();
            service.setQAManager( mgr );
            service.setProperty( "WS_CONNECTOR_ADDRESS",
                "ianywhere.connector.globalweather\\" );

            // Make a request to get weather for Beijing
            WSResult r = service.asyncGetWeather( "Beijing", "China" );

            // Display the request ID so that it can be used by ShowWeather
            System.out.println( "Request ID: " + r.getRequestID() );

            // QAnywhere finalization
            mgr.stop();
            mgr.close();

        } catch( Exception exc ) {
            System.out.println( exc.getMessage() );
        }
    }
}
```

The second application, called ShowWeather, shows the weather conditions for a given request ID:

```
import ianywhere.qanywhere.client.*;
import ianywhere.qanywhere.ws.*;
import com.myweather.GlobalWeatherSoap;

class ShowWeather
{
    public static void main( String [] args ) {
        try {
            // QAnywhere initialization
            QAManager mgr = QAManagerFactory.getInstance().createQAManager();
            mgr.open( AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT );
            mgr.start();

            // Instantiate the web service proxy
            GlobalWeatherSoap service = new GlobalWeatherSoap();
```

```

        service.setQAManager( mgr );

        // Get the response for the specified request ID
        WSResult r = service.getResult( args[0] );
        if( r.getStatus() == WSStatus.STATUS_RESULT_AVAILABLE ) {
            System.out.println( "The weather is " + r.getStringValue
                ( "GetWeatherResult" ) );
            r.acknowledge();
        } else {
            System.out.println( "Response not available" );
        }

        // QAnywhere finalization
        mgr.stop();
        mgr.close();

    } catch( Exception exc ) {
        System.out.println( exc.getMessage() );
    }
}

```

Compile the application and the service binding class:

```

javac -classpath ":%sqlany10%\java\iawsrt.jar;%sqlany10%\java\qaclient.jar"
com\myweather\GlobalWeatherSoap.java RequestWeather.java
javac -classpath ":%sqlany10%\java\iawsrt.jar;%sqlany10%\java\qaclient.jar"
com\myweather\GlobalWeatherSoap.java ShowWeather.java

```

### Create QAnywhere message stores and start a QAnywhere Agent

Your mobile web service application requires a client message store on each mobile device. It also requires a server message store, but this example uses the QAnywhere sample server message store.

To create a client message store, create a SQL Anywhere database with the dbinit utility and then run the QAnywhere Agent to set it up as a client message store:

```

dbinit -n -i qanywhere.db
qaagent -q -si -c "dbf=qanywhere.db"

```

Start the QAnywhere Agent to connect to your client message store. The following must all be on one command line:

```

qaagent
-c "dbf=qanywhere.db;eng=qanywhere;uid=ml_qa_user;pwd=qanywhere"
-policy automatic

```

Start the MobiLink server. This example uses the QAnywhere sample database as the server message store. The following must all be on one command line:

```

mlsrv10
-m
-zu+
-c "dsn=QAnywhere 10 Demo;uid=ml_server;pwd=sql;start=dbsrv10
-xs http(port=8080)"
-v+
-ot qanyserv.mls

```

For more information about these components, see:

- ◆ “Setting up the client message store” on page 33
- ◆ “Setting up the server message store” on page 30
- ◆ “Running the QAnywhere Agent” on page 35
- ◆ “Starting the MobiLink server for QAnywhere messaging” on page 31

### **Create a web service connector**

You must create a web service connector that listens for QAnywhere messages sent to the GetWeather web service, makes web service calls when messages arrive, and sends back responses to the originating client.

Open Sybase Central and connect to your server message store. To create your web service connector, choose File ► New Connector. When the Connector wizard appears, choose Web Services. In the wizard pages, you must set the following properties to match the mobile applications you created earlier in the example:

- ◆ In the Connector Name page, enter the Connector Name **ianywhere.connector.globalweather**
- ◆ In the Communication Parameters page, enter the URL **<http://www.myweather.com/GetWeather>**

---

CHAPTER 10

# QAnywhere Properties

## Contents

Message headers and message properties ..... 206  
Client message store properties ..... 215  
Server properties ..... 222

### About this chapter

This chapter describes the message properties and client message store properties that you can use in QAnywhere transmission rules and applications.

## Message headers and message properties

QAnywhere messages consist of the following parts:

- ◆ headers
- ◆ properties
- ◆ content

Message properties can be referenced in transmission rules and delete rules or in your application.

The following sections describe message headers and properties, and how you can set them in QAnywhere messages.

### Notes

- ◆ Message headers, message properties, and message content cannot be altered after the message is sent.
- ◆ You can read message headers, message properties, and message content after a message is received. If you are using the QAnywhere SQL API, these become unreadable after a commit or rollback occurs.
- ◆ The content is unreadable after acknowledgement or commit in all APIs.

## Message headers

All QAnywhere messages support the same set of header fields. Header fields contain values that are used by both clients and providers to identify and route messages.

The following message headers are pre-defined. How you use them depends on the type of client application you have.

- ◆ **Message ID** Read-only. The message ID of the new message. This header has a value only after the message is sent. See:
  - ◆ .NET API: [“MessageID property” on page 318](#)
  - ◆ C++ API: [“getMessageID function” on page 474](#) and [“setMessageID function” on page 484](#)
  - ◆ Java API: [“getMessageID method” on page 577](#)
  - ◆ SQL API: [“ml\\_qa\\_createmessage” on page 666](#) and [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ **Message creation timestamp** Read-only. The Timestamp header field contains the time a message was created. It is a coordinated universal time (UTC). It is not the time the message was actually transmitted, because the actual send may occur later due to transactions or other client-side queuing of messages. You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it. See:
  - ◆ .NET API: [“Timestamp property” on page 319](#)
  - ◆ C++ API: [“getTimestamp function” on page 478](#) and [“setTimestamp function” on page 486](#)
  - ◆ Java API: [“getTimestamp method” on page 581](#)
  - ◆ SQL API: [“ml\\_qa\\_gettimestamp” on page 641](#)

- ◆ **Reply-to address** Read-write. The reply address as VARCHAR(128) or NULL if it does not exist. You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it. See:
  - ◆ .NET API: [“ReplyToAddress property” on page 319](#)
  - ◆ C++ API: [“getReplyToAddress function” on page 476](#) and [“setReplyToAddress function” on page 485](#)
  - ◆ Java API: [“getReplyToAddress method” on page 579](#) and [“setReplyToAddress method” on page 587](#)
  - ◆ SQL API: [“ml\\_qa\\_getreplytoaddress” on page 640](#) and [“ml\\_qa\\_setreplytoaddress” on page 645](#)
- ◆ **Message address** Read-write. The QAnywhere message address as VARCHAR(128). QAnywhere message addresses take the form *id/queue-name*. You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it. See:
  - ◆ .NET API: [“Address property” on page 316](#)
  - ◆ C++ API: [“getAddress function” on page 469](#) and [“setAddress function” on page 480](#)
  - ◆ Java API: [“getAddress method” on page 572](#) and [“setAddress method” on page 582](#)
  - ◆ SQL API: [“ml\\_qa\\_getaddress” on page 636](#) and [“ml\\_qa\\_setaddress” on page 636](#)
- ◆ **Redelivered state of message** Read-only. The redelivered value as BIT. A value of 1 indicates that the message is being redelivered; 0 indicates that it is not being redelivered.

A message may be redelivered if it was previously received but not acknowledged. For example, the message was received but the application receiving the message did not complete processing the message content before it crashed. In these cases, QAnywhere marks the message as redelivered to alert the receiver that the message might be partly processed.

For example, assume that the receipt of a message occurs in three steps:

1. An application using a non-transactional QAnywhere manager receives the message.
2. The application writes the message content and message ID to a database table called T1, and commits the change.
3. The application acknowledges the message.

If the application fails between steps 1 and 2 or between steps 2 and 3, the message is redelivered when the application restarts.

If the failure occurs between steps 1 and 2, you should process the redelivered message by running steps 2 and 3. If the failure occurs between steps 2 and 3, then the message is already processed and you only need to acknowledge it.

To determine what happened when the application fails, you can have the application call `ml_qa_getredelivered` to check if the message has been previously redelivered. Only messages that are redelivered need to be looked up in table T1. This is more efficient than having the application access the received message's message ID to check whether the message is in the table T1, because application failures are rare.

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

See:

- ◆ .NET API: [“Redelivered property” on page 318](#)
- ◆ C++ API: [“getRedelivered function” on page 475](#) and [“setRedelivered function” on page 484](#)
- ◆ Java API: [“getRedelivered method” on page 579](#)
- ◆ SQL API: [“ml\\_qa\\_getredelivered” on page 639](#)
  
- ◆ **Expiration of message** Read-only except in the SQL API, where it is read-write. The expiration time as `TIMESTAMP`. Returns `NULL` if there is no expiration. A message expires if it is not received by the intended recipient in the specified time. The message may then be deleted using default QAnywhere delete rules. You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it. See:
  - ◆ .NET API: [“Expiration property” on page 317](#)
  - ◆ C++ API: [“getExpiration function” on page 471](#)
  - ◆ Java API: [“getExpiration method” on page 574](#)
  - ◆ SQL API: [“ml\\_qa\\_getexpiration” on page 637](#) and [“ml\\_qa\\_setexpiration” on page 642](#)
  
- ◆ **Priority of message** Read-write. The QAnywhere API defines ten levels of priority value, with 0 as the lowest priority and 9 as the highest. Clients should consider priorities 0-4 as gradations of normal priority and priorities 5-9 as gradations of expedited priority. You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it. See:
  - ◆ .NET API: [“Priority property” on page 318](#)
  - ◆ C++ API: [“getPriority function” on page 474](#)
  - ◆ Java API: [“getPriority method” on page 577](#)
  - ◆ SQL API: [“ml\\_qa\\_getpriority” on page 638](#)
  
- ◆ **Message ID of a message for which this message is a reply** Read-write. The in-reply-to ID as `VARCHAR(128)`. A client can use the `InReplyToID` header field to link one message with another. A typical use is to link a response message with its request message. The in-reply-to ID is the ID of the message that this message is replying to. You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it. See:
  - ◆ .NET API: [“InReplyToID property” on page 317](#)
  - ◆ C++ API: [“getInReplyToID function” on page 472](#)
  - ◆ Java API: [“getInReplyToID method” on page 575](#)
  - ◆ SQL API: [“ml\\_qa\\_getinreplytoid” on page 637](#)

Some message headers can be used in transmission rules. For details, see [“Variables defined by the rule engine” on page 231](#).

- ◆ C++ API: [“QAMessage class” on page 466](#)
- ◆ Java API: [“Interface QAMessage” on page 570](#)
- ◆ SQL API: [“Message headers” on page 636](#)

## Message properties

Each message contains a built-in facility for supporting application-defined property values. These message properties allow you to implement application-defined message filtering.

Message properties are name-value pairs that you can optionally insert into messages to provide structure. For example, in the .NET API the pre-defined message property `ias_Originator`, identified by the constant `MessageProperties.ORIGINATOR`, provides the message store ID that sent the message. Message properties can be used in transmission rules to determine the suitability of a message for transmission.

There are two types of message property:

- ◆ **Pre-defined message properties** These message properties are always prefixed with `ias_` or `IAS_`.
- ◆ **Custom message properties** These are message properties that you defined. You cannot prefix them with `ias_` or `IAS_`.

In either case, you access message store properties using `get` and `set` methods and pass the name of the pre-defined or custom property as the first parameter.

☞ For more information, see [“Managing message properties” on page 211](#).

## Pre-defined message properties

Some message properties have been pre-defined for your convenience. Pre-defined properties can be read but should not be set. The predefined message properties are:

- ◆ **ias\_Adapters** For network status notification messages, a list of network adapters that can be used to connect to the MobiLink server. The list is a string and is delimited by a vertical bar.
- ◆ **ias\_DeliveryCount** Int. The number of attempts that have been made so far to deliver the message.
- ◆ **ias\_MessageType** Int. Indicates the type of the message. The message types can be:

Value	Message type	Description
0	REGULAR	If a message does not have the <code>ias_MessageType</code> property set, it is a regular message.
13	PUSH_NOTIFICATION	When a push notification is received from the server, a message of type <code>PUSH_NOTIFICATION</code> is sent to the system queue. See <a href="#">“Notifications of push notification” on page 53</a> .
14	NETWORK_STATUS_NOTIFICATION	When there is a change in network status, a message of this type is sent to the system queue. See <a href="#">“Network status notifications” on page 52</a> .

- ◆ **ias\_RASNames** String. For network status notification messages, a list of RAS entry names that can be used to connect to the MobiLink server. The list is delimited by a vertical bar.

- ◆ **ias\_NetworkStatus** Int. For network status notification messages, the state of the network connection. The value is 1 if connected, 0 otherwise.
- ◆ **ias\_Originator** String. The message store ID of the originator of the message.
- ◆ **ias\_Status** Int. The current status of the message. This property is not supported in the SQL API. The values can be:

Status Code	Description
1	Pending - The message has been sent but not received.
10	Receiving - The message is in the process of being received, or it was received but not acknowledged.
20	Final - The message has achieved a final state.
30	Expired - The message was not received before its expiration time has passed.
40	Cancelled - The message has been cancelled.
50	Unreceivable - The message is either malformed, or there were too many failed attempts to deliver it.
60	Received - The message has been received and acknowledged.

There are constants for the status values. See:

- ◆ .NET API: [“StatusCodes enumeration” on page 340](#)
- ◆ C++ API: [“StatusCodes class” on page 498](#)
- ◆ Java API: [“Interface StatusCodes” on page 598](#)
- ◆ **ias\_StatusTime** The time at which the message became its current status. It is in units that are natural for the platform. It is a local time. In the C++ API, for Windows and PocketPC platforms, the timestamp is the SYSTEMTIME, converted to a FILETIME, which is copied to a qa\_long value. This property is not supported in the SQL API.

API	This property returns...
.NET	DateTime
C++	string
Java	java.util.Date object

### Message property constants

The QAnywhere APIs for .NET, C++, and Java provide constants for specifying message properties. See:

- ◆ .NET API: [“MessageProperties members” on page 245](#)
- ◆ C++ API: [“MessageProperties class” on page 394](#)
- ◆ Java API: [“Interface MessageProperties” on page 505](#)

## Custom message properties

QAnywhere allows you to define message properties using the C++, Java, or .NET APIs. Custom message properties allow you to create name-value pairs that you associate with an object. For example:

```
msg.SetStringProperty("Product", "widget");
msg.SetFloatProperty("Price", 1.00);
msg.SetIntProperty("Quantity", 10);
```

Message property names are case insensitive. You can use a sequence of letters, digits and underscores, but the first character must be a letter. The following names are reserved and may not be used as message property names:

- ◆ NULL
- ◆ TRUE
- ◆ FALSE
- ◆ NOT
- ◆ AND
- ◆ OR
- ◆ BETWEEN
- ◆ LIKE
- ◆ IN
- ◆ IS
- ◆ ESCAPE
- ◆ Any name beginning with **ias\_**

## Managing message properties

The following QAMessage methods can be used to manage message properties.

You can get and set custom properties, but should only get pre-defined properties.

### .NET methods to manage message properties

- ◆ Object GetProperty( String name )
- ◆ void SetProperty( String name, Object value )
- ◆ boolean GetBooleanProperty( String name )
- ◆ void SetBooleanProperty( String name, boolean value )
- ◆ byte GetByteProperty( String name )
- ◆ void SetByteProperty( String name, byte value )
- ◆ short GetShortProperty( String name )
- ◆ void SetShortProperty( String name, short value )
- ◆ int GetIntProperty( String name )
- ◆ void SetIntProperty( String name, int value )
- ◆ long GetLongProperty( String name )
- ◆ void SetLongProperty( String name, long value )
- ◆ float GetFloatProperty( String name )
- ◆ void SetFloatProperty( String name, float value )

- ◆ double GetDoubleProperty( String name )
- ◆ void SetDoubleProperty( String name, double value )
- ◆ String GetStringProperty( String name )
- ◆ void SetStringProperty( String name, String value )
- ◆ IEnumerable GetPropertyNames()
- ◆ void ClearProperties()
- ◆ PropertyType GetPropertyType( string propName )
- ◆ bool PropertyExists( string propName )

☞ For more information, see [“QAMessage interface” on page 314](#).

### C++ methods to manage message properties

- ◆ qa\_bool getBooleanProperty( qa\_const\_string name, qa\_bool \* value )
- ◆ qa\_bool setBooleanProperty( qa\_const\_string name, qa\_bool value )
- ◆ qa\_bool getByteProperty( qa\_const\_string name, qa\_byte \* value )
- ◆ qa\_bool setByteProperty( qa\_const\_string name, qa\_byte value )
- ◆ qa\_bool getShortProperty( qa\_const\_string name, qa\_short \* value )
- ◆ qa\_bool setShortProperty( qa\_const\_string name, qa\_short value )
- ◆ qa\_bool getIntProperty( qa\_const\_string name, qa\_int \* value )
- ◆ qa\_bool setIntProperty( qa\_const\_string name, qa\_int value )
- ◆ qa\_bool getLongProperty( qa\_const\_string name, qa\_long \* value )
- ◆ qa\_bool setLongProperty( qa\_const\_string name, qa\_long value )
- ◆ qa\_bool getFloatProperty( qa\_const\_string name, qa\_float \* value )
- ◆ qa\_bool setFloatProperty( qa\_const\_string name, qa\_float value )
- ◆ qa\_bool getDoubleProperty( qa\_const\_string name, qa\_double \* value )
- ◆ qa\_bool setDoubleProperty( qa\_const\_string name, qa\_double value )
- ◆ qa\_int getStringProperty( qa\_const\_string name, qa\_string value, qa\_int len )
- ◆ qa\_bool setStringProperty( qa\_const\_string name, qa\_const\_string value )
- ◆ void QAMessage::clearProperties()
- ◆ qa\_short QAMessage::getPropertyType( qa\_const\_string name )
- ◆ qa\_bool QAMessage::propertyExists( qa\_const\_string name )
- ◆

☞ For more information, see [“QAMessage class” on page 466](#).

### Java methods to manage message properties

- ◆ void clearProperties()
- ◆ boolean getBooleanProperty( String name )
- ◆ void setBooleanProperty( String name, boolean value )
- ◆ byte getByteProperty( String name )
- ◆ void setByteProperty( String name, byte value )
- ◆ double getDoubleProperty( String name )
- ◆ void setDoubleProperty( String name, double value )
- ◆ java.util.Date getExpiration() void setFloatProperty( String name, float value )
- ◆ float getFloatProperty( String name )
- ◆ int getIntProperty( String name )
- ◆ void setIntProperty( String name, int value )

- ◆ long getLongProperty( String name )
- ◆ void setLongProperty( String name, long value )
- ◆ Object getProperty( String name )
- ◆ void setProperty( String name, Object value )
- ◆ java.util.Enumeration getPropertyNames()
- ◆ short getPropertyType( String name )
- ◆ short getShortProperty( String name )
- ◆ void setShortProperty( String name, short value )
- ◆ String getStringProperty( String name )
- ◆ void setStringProperty( String name, String value )
- ◆ boolean propertyExists( String name )

☞ For more information, see [“Interface QAMessage” on page 570.](#)

### SQL stored procedures to manage message properties

- ◆ ml\_qa\_getbooleanproperty
- ◆ ml\_qa\_getbyteproperty
- ◆ ml\_qa\_getdoubleproperty
- ◆ ml\_qa\_getfloatproperty
- ◆ ml\_qa\_getintproperty
- ◆ ml\_qa\_getlongproperty
- ◆ ml\_qa\_getpropertynames
- ◆ ml\_qa\_getshortproperty
- ◆ ml\_qa\_getstringproperty
- ◆ ml\_qa\_setbooleanproperty
- ◆ ml\_qa\_setbyteproperty
- ◆ ml\_qa\_setdoubleproperty
- ◆ ml\_qa\_setfloatproperty
- ◆ ml\_qa\_setfloatproperty
- ◆ ml\_qa\_setintproperty
- ◆ ml\_qa\_setlongproperty
- ◆ ml\_qa\_setshortproperty
- ◆ ml\_qa\_setstringproperty

☞ For more information, see [“Message properties” on page 645.](#)

### Example

```
// C++ example.
QAManagerFactory factory;
QAManager * mgr = factory->createQAManager( NULL );
mgr->open(AcknowledgementMode::EXPLICIT_ACKNOWLEDGEMENT);
QAMessage * msg = mgr->createTextMessage();
msg->setStringProperty( "tm_Subject", "Some message subject." );
mgr->putMessage( "myqueue", mgr );

// C# example.
QAManager mgr = QAManagerFactory.Instance.CreateQAManager(null);
mgr.Open(AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT);
QAMessage msg = mgr.CreateTextMessage();
msg.SetStringProperty( "tm_Subject", "Some message subject." );
mgr.PutMessage( "myqueue", msg );
```

```
// Java example
QAManager mgr = QAManagerFactory.getInstance().createQAManager(null);
mgr.open(AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT);
QAMessage msg = mgr.createTextMessage();
msg.setStringProperty("tm_Subject", "Some message subject.");
mgr.putMessage("myqueue", mgr);

-- SQL example
begin
  DECLARE @msgid VARCHAR(128);
  SET @msgid = ml_qa_createmessage();
  CALL ml_qa_setfloatproperty( @msgid, 'myfloatproperty1', -1.3e-5 );
  CALL ml_qa_setfloatproperty( @msgid, 'myfloatproperty2', 1.3e5 );
  CALL ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  COMMIT;
end
```

---

## Client message store properties

There are two types of client message store property:

- ◆ **Pre-defined message store properties** These message store properties are always prefixed with `ias_` or `IAS_`.
- ◆ **Custom message store properties** These are message store properties that you defined. You cannot prefix them with `ias_` or `IAS_`.

In either case, you access client message store properties using `get` and `set` methods defined in the appropriate class and pass the name of the pre-defined or custom property as the first parameter.

☞ For more information, see [“Managing client message store properties” on page 219](#).

You can also use message store properties in transmission rules, delete rules, and message selectors. See:

- ◆ [“QAnywhere Transmission and Delete Rules” on page 225](#)

### Pre-defined client message store properties

A number of client message store properties have been pre-defined for your convenience. The predefined message store properties are:

- ◆ **ias\_Adapters** A list of network adapters that can be used to connect to the MobiLink server. The list is a string and is delimited by a vertical bar.
- ◆ **ias\_MaxDeliveryAttempts** When defined, the maximum number of times that a message can be received without being acknowledged before its status is set to `UNRECEIVABLE`. By default, this property is not defined and is equivalent to a value of `-1`, which means that the client library will continue to attempt to deliver an unacknowledged message forever.
- ◆ **ias\_MaxUploadSize** The upload increment size. By default, QAnywhere uploads messages in increments of 256K, but no matter what the upload size is set to, QAnywhere will send at least one message per increment and will not split messages. This property is identical to the `qaagent -iu` option. See [“-iu option” on page 153](#).
- ◆ **ias\_Network** Information about the current network in use. This property can be read but should not be set. `ias_Network` is a special property. It has a number of built-in attributes that provide information regarding the current network that is being used by the device. The following attributes are automatically set by QAnywhere:
  - ◆ **ias\_Network.Adapter** The current name of the network card, if any. (The name of the network card that is assigned to the `Adapter` attribute is displayed in the Agent window when the network connection is established.)
  - ◆ **ias\_Network.RAS** The current RAS entry name, if any.
  - ◆ **ias\_Network.IP** The current IP address assigned to the device, if any.

- ◆ **ias\_Network.MAC** The current MAC address of the network card being used, if any.
  - ◆ **ias\_RASNames** String. A list of RAS entry names that can be used to connect to the MobiLink server. The list is delimited by a vertical bar.
  - ◆ **ias\_StoreID** The message store ID.
  - ◆ **ias\_StoreInitialized** True if this message stores has successfully been initialized for QAnywhere messaging; otherwise False.
- ☞ See “-si option” on page 169.
- ◆ **ias\_StoreVersion** The QAnywhere-defined version number of this message store.

For information about managing pre-defined message properties, see:

- ◆ C++ API: “[MessageStoreProperties class](#)” on page 401
- ◆ .NET API: “[MessageStoreProperties class](#)” on page 253
- ◆ Java API: “[Interface MessageStoreProperties](#)” on page 510
- ◆ SQL API: “[Message store properties](#)” on page 664

### Custom client message store properties

QAnywhere allows you to define your own client message store properties using the QAnywhere C++, Java, SQL or .NET APIs. These properties are shared between applications connected to the same message store. They are also synchronized to the server message store so that they are available to server-side transmission rules for this client.

Client message store property names are case insensitive. You can use a sequence of letters, digits, and underscores, but the first character must be a letter. The following names are reserved and may not be used as message store property names:

- ◆ NULL
- ◆ TRUE
- ◆ FALSE
- ◆ NOT
- ◆ AND
- ◆ OR
- ◆ BETWEEN
- ◆ LIKE
- ◆ IN
- ◆ IS
- ◆ ESCAPE
- ◆ Any name beginning with **ias\_**

## Using custom client message store property attributes

Client message store properties can have attributes that you define. An attribute is defined by appending a dot after the property name followed by the attribute name. The main use of this feature is to be able to use information about your network in your transmission rules.

### Example

Following is a simple example of how to set custom client message store property attributes. In this example, the Object property has two attributes: Shape and Color. The value of the Shape attribute is Round and the value of the Color attribute is Blue.

```
// C++ example.
mgr->setStringStoreProperty( "Object.Shape", "Round" );
mgr->setStringStoreProperty( "Object.Color", "Blue" );

// C# example.
mgr.SetStringStoreProperty( "Object.Shape", "Round" );
mgr.SetStringStoreProperty( "Object.Color", "Blue" );

// Java example
mgr.setStringStoreProperty( "Object.Shape", "Round" );
mgr.setStringStoreProperty( "Object.Color", "Blue" );

-- SQL example
BEGIN
    CALL ml_qa_setstoreproperty( 'Object.Shape', 'Round' );
    CALL ml_qa_setstoreproperty( 'Object.Color', 'Blue' );
    COMMIT;
END
```

All client message store properties have a Type attribute that initially has no value. The value of the Type attribute must be the name of another property. When setting the Type attribute of a property, the property inherits the attributes of the property being assigned to it. In the following example, the Object property inherits the attributes of the Circle property. Therefore, the value of Object.Shape is Round and the value of Object.Color is Blue.

```
// C++ example
QAManager qa_manager;
qa_manager->setStoreStringProperty( "Circle.Shape", "Round" );
qa_manager->setStoreStringProperty( "Circle.Color", "Blue" );
qa_manager->setStoreStringProperty( "Object.Type", "Circle" );

// C# example
QAManager qa_manager;
qa_manager.SetStringStoreProperty( "Circle.Shape", "Round" );
qa_manager.SetStringStoreProperty( "Circle.Color", "Blue" );
qa_manager.SetStringStoreProperty( "Object.Type", "Circle" );

// Java example
QAManager qa_manager;
qa_manager.setStringStoreProperty( "Circle.Shape", "Round" );
qa_manager.setStringStoreProperty( "Circle.Color", "Blue" );
qa_manager.setStringStoreProperty( "Object.Type", "Circle" );

-- SQL example
BEGIN
    CALL ml_qa_setstoreproperty( 'Circle.Shape', 'Round' );
    CALL ml_qa_setstoreproperty( 'Circle.Color', 'Blue' );
    CALL ml_qa_setstoreproperty( 'Object.Type', 'Circle' );
```

```

        COMMIT ;
    END

```

## Example

The following C# example shows how you can use message store properties to provide information about your network to your transmission rules.

Assume you have a Windows laptop that has the following network connectivity options: LAN, Wireless LAN, and Wireless WAN. Access to the network via LAN is provided by a network card named My LAN Card. Access to the network via Wireless LAN is provided by a network card named My Wireless LAN Card. Access to the network via Wireless WAN is provided by a network card named My Wireless WAN Card.

Assume you want to develop a messaging application that sends all messages to the server when connected using LAN or Wireless LAN and only high priority messages when connected using Wireless WAN. You define high priority messages as those whose priority is greater than or equal to 7.

First, find the names of your network adapters. The names of network adapters are fixed when the card is plugged in and the driver is installed. To find the name of a particular network card, connect to the network through that adapter, and then run `qaagent` with the `-vn` option. The QAnywhere Agent displays the network adapter name, as follows:

```
"Listener thread received message '[netstat] network-adapter-name !...'
```

Next, define three client message store properties for each of the network types: LAN, WLAN, and WWAN. Each of these properties will be assigned a `Cost` attribute. The `Cost` attribute is a value between 1 and 3 and represents the cost incurred when using the network. A value of 1 represents the lowest cost.

```

QAManager    qa_manager;
qa_manager.SetStoreProperty( "LAN.Cost", "1" );
qa_manager.SetStoreProperty( "WLAN.Cost", "2" );
qa_manager.SetStoreProperty( "WWAN.Cost", "3" );

```

Next, define three client message store properties, one for each network card that will be used. The property name must match the network card name. Assign the appropriate network classification to each property by assigning the network type to the `Type` attribute. Each property will therefore inherit the attributes of the network types assigned to them.

```

QAManager    qa_manager;
qa_manager.SetStoreProperty( "My LAN Card.Type", "LAN" );
qa_manager.SetStoreProperty( "My Wireless LAN Card.Type", "WLAN" );
qa_manager.SetStoreProperty( "My Wireless WAN Card.Type", "WWAN" );

```

When network connectivity is established, QAnywhere automatically defines the `Adapter` attribute of the `ias_Network` property to one of My LAN Card, My Wireless LAN Card or My Wireless WAN Card, depending on the network in use. Similarly, it automatically sets the `Type` attribute of the `ias_Network` property to one of My LAN Card, My Wireless LAN Card, or My Wireless WAN Card so that the `ias_Network` property inherits the attributes of the network being used.

Finally, create the following transmission rule.

```
automatic=ias_Network.Cost < 3 or ias_Priority >= 7
```

☞ For more information about transmission rules, see [“QAnywhere Transmission and Delete Rules”](#) on page 225.

## Enumerating client message store properties

The QAnywhere .NET, C++, and Java APIs can provide an enumeration of predefined and custom client message store properties.

### .NET example

☞ For more information, see [“GetStorePropertyNames method”](#) on page 297.

```
// qaManager is a QAManager instance.
IEnumerator propertyNames = qaManager.GetStorePropertyNames();
```

### C++ example

☞ For more information, see [“beginEnumStorePropertyNames function”](#) on page 433.

```
// qaManager is a QAManager instance.
qa_store_property_enum_handle handle = qaManager->beginEnumStorePropertyNames
();
qa_char propertyName[256];
if( handle != qa_null ) {
    while( qaManager->nextStorePropertyName( handle, propertyName, 255 ) !=
-1 ) {
        // Do something with the message store property name.
    }
    // Message store properties cannot be set after
    // the beginEnumStorePropertyNames call
    // and before the endEnumStorePropertyNames call.
    qaManager->endEnumStorePropertyNames(handle);
}
```

### Java example

☞ For more information, see [“getStorePropertyNames method”](#) on page 556.

```
// qaManager is a QAManager instance.
Enumeration propertyNames = qaManager.getStorePropertyNames();
```

## Managing client message store properties

Client message store properties can be set in your client application for each client message store.

☞ See [“Managing client message store properties in your application”](#) on page 220.

Client message store properties can be used in transmission rules to filter messages to the client or used in delete rules to determine messages to add.

☞ See [“QAnywhere Transmission and Delete Rules”](#) on page 225.

Client message store properties can also be specified in server management messages, and stored on the server message store.

☞ See [“About server management requests”](#) on page 92.

## Managing client message store properties in your application

The following QAManagerBase methods can be used to get and set client message store properties.

### C++ methods to manage client message store properties

- ◆ qa\_bool getBooleanStoreProperty( qa\_const\_string name, qa\_bool \* value )
- ◆ qa\_bool setBooleanStoreProperty( qa\_const\_string name, qa\_bool value )
- ◆ qa\_bool getByteStoreProperty( qa\_const\_string name, qa\_byte \* value )
- ◆ qa\_bool setByteStoreProperty( qa\_const\_string name, qa\_byte value )
- ◆ qa\_bool getShortStoreProperty( qa\_const\_string name, qa\_short \* value )
- ◆ qa\_bool setShortStoreProperty( qa\_const\_string name, qa\_short value )
- ◆ qa\_bool getIntStoreProperty( qa\_const\_string name, qa\_int \* value )
- ◆ qa\_bool setIntStoreProperty( qa\_const\_string name, qa\_int value )
- ◆ qa\_bool getLongStoreProperty( qa\_const\_string name, qa\_long \* value )
- ◆ qa\_bool setLongStoreProperty( qa\_const\_string name, qa\_long value )
- ◆ qa\_bool getFloatStoreProperty( qa\_const\_string name, qa\_float \* value )
- ◆ qa\_bool setFloatStoreProperty( qa\_const\_string name, qa\_float value )
- ◆ qa\_bool getDoubleStoreProperty( qa\_const\_string name, qa\_double \* value )
- ◆ qa\_bool setDoubleStoreProperty( qa\_const\_string name, qa\_double value )
- ◆ qa\_int getStringStoreProperty( qa\_const\_string name, qa\_string value, qa\_int len )
- ◆ qa\_bool setStringStoreProperty( qa\_const\_string name, qa\_const\_string value )
- ◆ qa\_store\_property\_enum\_handle QAManagerBase::beginEnumStorePropertyNames()
- ◆ virtual qa\_int QAManagerBase::nextStorePropertyName( qa\_store\_property\_enum\_handle h, qa\_string buffer, qa\_int bufferSize)
- ◆ virtual void QAManagerBase::endEnumStorePropertyNames(qa\_store\_property\_enum\_handle h)

☞ See [“QAManagerBase class”](#) on page 432.

### C# methods to manage client message store properties

- ◆ Object GetStoreProperty( String name )
- ◆ void SetStoreProperty( String name, Object value )
- ◆ boolean GetBooleanStoreProperty( String name )
- ◆ void SetBooleanStoreProperty( String name, boolean value )
- ◆ byte GetByteStoreProperty( String name )

- ◆ long getLongStoreProperty( String name )
- ◆ void setLongStoreProperty( String name, long value )
- ◆ short getShortStoreProperty( String name )
- ◆ void setShortStoreProperty( String name, short value )
- ◆ void setStringStoreProperty( String name, String value )
- ◆ String getStringStoreProperty( String name )
- ◆ java.util.Enumeration getStorePropertyNames()

☞ See [“Interface QAManagerBase” on page 540](#).

### SQL stored procedures to manage client message store properties

- ◆ ml\_qa\_getstoreproperty
- ◆ ml\_qa\_setstoreproperty

☞ See [“Message store properties” on page 664](#).

## Server properties

You can set server properties in Sybase Central or with a server management request. In all cases, the server properties are stored in the database. See:

- ◆ [“Setting server properties with a server management request” on page 114](#)
- ◆ [“Setting server properties with Sybase Central” on page 223](#)

### Server properties

- ◆ **ianywhere.qa.server.autoRulesEvaluationPeriod** The time in milliseconds between evaluations of rules, including message transmission and persistence rules. Since, typically, rules are evaluated on the fly as messages are transmitted to the server store, the rule evaluation period is only for rules that are timing-sensitive. The default value is **60000** (one minute).
- ◆ **ianywhere.qa.compressionLevel** The default amount of compression applied to each message received by a QAnywhere connector. The compression is an integer between 0 and 9, with 0 being no compression and 9 being the most compression. The default is **0**.

If you also set the compression level for a connector in the connector properties file, this setting is overridden for that connector. For more information, see [“JMS connector properties” on page 132](#).

- ◆ **ianywhere.qa.server.connectorPropertiesFiles**

**Deprecated feature**

Replaced by Sybase Central.

A list of one or more files that specify the configuration of QAnywhere connectors to an external message system such as JMS. The default is no connectors.

 For more information, see [“JMS Connectors” on page 127](#).

- ◆ **ianywhere.qa.server.disableNotifications** Set this to true to disable notification from the server about pending messages. This disables the processing on the server that is required to initiate notifications to clients when messages are waiting on the server for those clients. Set to true in any setup where notifications cannot be sent from the server, such as when firewall restrictions make notifications impossible. The default is false.
- ◆ **ianywhere.qa.server.logLevel** The logging level of the messaging. The property value may be one of 1, 2, 3, or 4. 1 indicates that only message errors are logged. 2 additionally causes warnings to be logged. 3 additionally causes informational messages to be logged. 4 additionally causes more verbose informational messages to be logged, including details about each QAnywhere message that is transmitted with the MobiLink server. The default is **2**.

These logging messages are output to the MobiLink server console. If the `mlsrv10 -o` or `-ot` option was specified, the messages are output to the MobiLink server log file.

- ◆ **ianywhere.qa.server.id** Specifies the agent portion of the address to which to send server management requests. If this property is not set, this value is `ianywhere.server`.

- ◆ **ianywhere.qa.server.password.e** Specifies the password for authenticating server management requests. If this property is not set, the password is QAnywhere.

☞ See “[About server management requests](#)” on page 92.

- ◆ **ianywhere.qa.server.scheduleDateFormat** Specifies the date format used for server-side transmission rules. By default, the date format is yyyy-MM-dd.

Letter	Date component	Example
y	year	1996
M	month in year	July
d	day in month	10

- ◆ **ianywhere.qa.server.scheduleTimeFormat** Specifies the time format used for server-side transmission rules. By default, the time format is HH:mm:ss.

Letter	Date component	Example
a	AM/PM marker	PM
H	hour in day, a value between 0 and 23	0
k	hour in day, a value between 1 and 24	24
K	hour in AM/PM, a value between 0 and 11	0
h	hour in AM/PM, a value between 1 and 12	12
m	minute in hour	30
s	second in minute	55

- ◆ **ianywhere.qa.server.transmissionRulesFile**

**Deprecated feature**  
Replaced by Sybase Central.

A file used to specify rules for governing the transmission and persistence of messages. By default, there are no filters for messages, and messages are deleted when the final status of the message has been transmitted to the message originator.

## Setting server properties with Sybase Central

- ◆ **To set server properties with Sybase Central**

1. Start Sybase Central:

- ◆ Choose Start ► Programs ► SQL Anywhere 10 ► Sybase Central.
  - ◆ From Connections, choose Connect with QAnywhere 10.
  - ◆ Specify an ODBC data source name or file, and a user ID and password if required. Click OK.
2. Under Server Store tasks in the left pane, choose Change Properties of this message store.
- The message store Properties dialog appears.

---

CHAPTER 11

# QAnywhere Transmission and Delete Rules

## Contents

Rule syntax ..... 226

Rule variables ..... 231

Message transmission rules ..... 234

Message delete rules ..... 239

### About this chapter

This chapter describes how to write transmission rules. You can create rules on the server to define which messages should be downloaded to the client and when they should be transmitted, and rules on the client to define which messages should be uploaded to the server and when they should be uploaded.

## Rule syntax

Rules have two parts: a schedule and a condition. The schedule defines when an event is to occur. The condition defines which messages are to be part of the event. For example, if the event is message transmission, then the schedule indicates when transmission will occur and the condition defines which messages will be included in the transmission. If the event is message deletion, then the schedule indicates when deleting will occur and the condition indicates which messages will be deleted.

### Rule syntax

Each rule has the following form:

```
schedules=condition
```

## Schedule syntax

### Schedule syntax

```
schedules : { AUTOMATIC | schedule-spec ,... }
```

```
schedule-spec :
```

```
{ START TIME start-time | BETWEEN start-time AND end-time }  
[ EVERY period { HOURS | MINUTES | SECONDS } ]  
[ ON { ( day-of-week, ... ) | ( day-of-month, ... ) } ]  
[ START DATE start-date ]
```

### Parameters

- ◆ **AUTOMATIC** For transmission rules, rules are evaluated when a message changes state or there is a change in network status. For delete rules, messages that satisfy the delete rule condition are deleted when a message transmission is initiated.
- ◆ **schedule-spec** Schedule specifications other than AUTOMATIC specify times when conditions are to be evaluated. At those scheduled times, the corresponding condition is evaluated.
- ◆ **START TIME** The first scheduled time for each day on which the event is scheduled. If a START DATE is specified, the START TIME refers to that date. If no START DATE is specified, the START TIME is on the current day (unless the time has passed) and each subsequent day (if the schedule includes EVERY or ON).
- ◆ **BETWEEN ... AND ...** A range of times during the day outside of which no scheduled times occur. If a START DATE is specified, the scheduled times do not occur until that date.
- ◆ **EVERY** An interval between successive scheduled events. Scheduled events occur only after the START TIME for the day, or in the range specified by BETWEEN ... AND.
- ◆ **ON** A list of days on which the scheduled events occur. The default is every day if EVERY is specified. Days can be specified as days of the week or days of the month.

Days of the week are Mon, Tues, and so on. You may also use the full forms of the day, such as Monday. You must use the full forms of the day names if the language you are using is not English, is not the

language requested by the client in the connection string, and is not the language that appears in the server window.

Days of the month are integers from 0 to 31. A value of 0 represents the last day of any month.

- ◆ **START DATE** The date on which scheduled events are to start occurring. The default is the current date.

## Usage

You can create more than one schedule for a given condition. This permits complex schedules to be implemented.

A schedule specification is recurring if its definition includes EVERY or ON; if neither of these reserved words is used, the schedule specifies at most a single time. An attempt to create a non-recurring schedule for which the start time has passed generates an error.

Each time a scheduled time occurs, the associated condition is evaluated and then the next scheduled time and date is calculated.

The next scheduled time is computed by inspecting the schedule or schedules, and finding the next schedule time that is in the future. If a schedule specifies every minute, and it takes 65 seconds to evaluate the conditions, it runs every two minutes. If you want execution to overlap, you must create more than one rule.

1. If the EVERY clause is used, find whether the next scheduled time falls on the current day, and is before the end of the BETWEEN ... AND range. If so, that is the next scheduled time.
2. If the next scheduled time does not fall on the current day, find the next date on which the event is to be executed.
3. Find the START TIME for that date, or the beginning of the BETWEEN ... AND range.

The QAnywhere schedule syntax is derived from the SQL Anywhere CREATE EVENT schedule syntax.

Keywords are case insensitive.

## See also

- ◆ [“CREATE EVENT statement” \[SQL Anywhere Server - SQL Reference\]](#)

## Example

The following sample server transmission rules file applies to the client identified by the client message store ID sample\_store\_id. It creates a dual schedule: high priority messages are sent once an hour. The schedule is every 1 hours and the condition is ias\_priority=9. Also, between the hours of 8 A.M. and 9 A.M., high priority messages are sent every minute.

```
[sample_store_id]
; This rule governs when messages are transmitted to the client
; store with id sample_store_id.
;
  every 1 hours = ias_priority=9
  between 8:00 and 9:00 every 1 minutes = iasPriority=9
```

## Condition syntax

QAnywhere conditions use a SQL-like syntax. Conditions are evaluated against messages in the message store. A condition evaluates to true, false, or unknown. If a condition is empty, all messages are judged to satisfy the condition. Conditions can be used in transmission rules, delete rules, and the QAnywhere programming APIs.

Keywords and string comparisons are case insensitive.

### Syntax

```

condition :
expression IS [ NOT ] NULL
| expression compare expression
| expression [ NOT ] BETWEEN expression AND expression
| expression [ NOT ] LIKE string [ ESCAPE character ]
| expression [ NOT ] IN ( string, ... )
| NOT condition
| condition AND condition
| condition OR condition
| ( condition )
    
```

```
compare: = > | < | >= | <= | <>
```

```

expression:
constant
| rule-variable
| -expression
| expression operator expression
| ( expression )
| rule-function ( expression, ... )
    
```

*integer*: An integer in the range  $-2^{63}$  to  $2^{63}-1$

*number*: A number in scientific notation in the range  $2.2250738585072e-308$  to  $1.79769313486231e+308$

*string*: A sequence of characters enclosed in single quotes. A single quote in a string is represented by two consecutive single quotes.

*constant*: *integer* | *number* | *string* | **TRUE** | **FALSE**

*operator*: + | - | \* | /

*rule-variable*:

See [“Rule variables” on page 231](#)

*rule-function*:

See [“Rule functions” on page 230](#)

### Parameters

- ◆ **BETWEEN** The BETWEEN condition can evaluate as true, false, or unknown. Without the NOT keyword, the condition evaluates as TRUE if *expression* is greater than or equal to the start expression and less than or equal to the end expression.

The NOT keyword reverses the meaning of the condition but leaves UNKNOWN unchanged.

The BETWEEN condition is equivalent to a combination of two inequalities:

[ **NOT** ] ( *expression* >= *start-expression* **AND** *arithmetic-expression* <= *end-expr* )

For example:

- ◆ age BETWEEN 15 AND 19 is equivalent to age >=15 AND age <= 19
- ◆ age NOT BETWEEN 15 AND 19 is equivalent to age < 15 OR age > 19.
- ◆ **IN** The IN condition evaluates according to the following rules:
  - ◆ True if *expression* is not null and equals at least one of the values in the list.
  - ◆ Unknown if *expression* is null and the values list is not empty, or if at least one of the values is null and expression does not equal any of the other values.
  - ◆ False if none of the values are null, and *expression* does not equal any of the values in the list.

The NOT keyword interchanges true and false.

For example:

- ◆ Country IN ( 'UK', 'US', 'France' ) is true for 'UK' and false for 'Peru'. It is equivalent to the following:

```
( Country = 'UK' )      \
OR ( Country = 'US' )  \
OR ( Country = 'France' )
```

- ◆ Country NOT IN ( 'UK', 'US', 'France' ) is false for 'UK' and true for 'Peru'. It is equivalent to the following:

```
NOT ( ( Country = 'UK' )      \
      OR ( Country = 'US' )   \
      OR ( Country = 'France' ) )
```

- ◆ **LIKE** The LIKE condition can evaluate as true, false, or unknown.

Without the NOT keyword, the condition evaluates as TRUE if *expression* matches the *like expression*. If either *expression* or *like expression* is NULL, this condition is unknown.

The NOT keyword reverses the meaning of the condition, but leaves UNKNOWN unchanged.

The *like expression* may contain any number of wildcards. The wildcards are:

Wildcard	Matches
_ (underscore)	Any one character
% (percent)	Any string of zero or more characters

For example:

- ◆ phone LIKE 12%3 is true for '123' or '12993' and false for '1234'

- ◆ `word LIKE 's_d'` is true for 'sad' and false for 'said'
- ◆ `phone NOT LIKE '12%3'` is false for '123' or '12993' and true for '1234'
- ◆ **ESCAPE CHARACTER** The ESCAPE CHARACTER is a single character string literal whose character is used to escape the special meaning of the wildcard characters (`_`, `%`) in *pattern*. For example:
  - ◆ `underscored LIKE '\_%' ESCAPE '\'` is true for '`_myvar`' and false for '`myvar`'.
- ◆ **IS NULL** The IS NULL condition evaluates to true if the rule-variable is unknown; otherwise it evaluates to false. The NOT keyword reverses the meaning of the condition. This condition cannot evaluate to unknown.

## Rule functions

You can use the following functions in transmission rules:

Syntax	Description
<b>DATEADD( <i>datepart</i>, <i>count</i>, <i>datetime</i> )</b>	Returns a datetime produced by adding a number of date parts to a datetime. The <i>datepart</i> can be one of year, quarter, month, week, day, hour, minute, or second. For example, the following example adds two months, resulting in the value 2006-07-02 00:00:00.0:  <code>DATEADD( month, 2, '2006/05/02' )</code>
<b>DATEPART( <i>datepart</i>, <i>date</i> )</b>	Returns the value of part of a datetime value. The <i>datepart</i> can be one of year, quarter, month, week, day, dayofyear, weekday, hour, minute, or second. For example, the following example gets the month May as a number, resulting in the value 5:  <code>DATEPART( month, '2006/05/02' )</code>
<b>DATETIME( <i>string</i> )</b>	Converts a string value to a datetime. The string must have the format 'yyyy-mm-dd hh:nn:ss'.
<b>LENGTH( <i>string</i> )</b>	Returns the number of characters in a string.
<b>SUBSTRING( <i>string</i>, <i>start</i>, <i>length</i> )</b>	Returns a substring of a string. The <i>start</i> is the start position of the substring to return, in characters. The <i>length</i> is the length of the substring to return, in characters.

### Example

The following delete rule deletes all messages that entered a final state more than 10 days ago:

```
every 1 hours = ias_Status >= ias_FinalState
    AND ias_StatusTime < DATEADD( day, -10, ias_CurrentTimestamp )
    AND ias_TransmissionStatus = 1
```

## Rule variables

QAnywhere rule variables can be used in the condition part of rules. You can use the following as rule variables:

- ◆ “Message properties” on page 209
- ◆ “Client message store properties” on page 215
- ◆ “Variables defined by the rule engine” on page 231

### Using properties as rule variables

Message properties and message store properties can be used as transmission rule variables. In both cases you can use pre-defined properties or you can create custom properties. If you have a message property and a message store property with the same name, the message property is used. To override this precedence, you can explicitly reference the property as follows:

- ◆ Preface a message store property name with `ias_Store`.
- ◆ Preface a message property name with `ias_Message`.

For example, the following automatic transmission rule selects all messages with the custom message property called `urgent` set to `yes`:

```
automatic = ias_Message.urgent = 'yes'
```

The following automatic transmission rule selects messages when the custom message store property `transmitNow` is set to `yes`:

```
automatic = ias_Store.transmitNow = 'yes'
```

### Variables defined by the rule engine

The following variables are defined by the rule engine:

- ◆ **ias\_Address** The address of the message. For example, `myclient\myqueue`.
- ◆ **ias\_Content** The body of the message. Character comparisons are done in the character set of the message store default. Searching content can significantly slow rule evaluation.
- ◆ **ias\_ContentSize** The size of the message content. If the message is a text message, this is the number of characters. If the message is binary, this is the number of bytes.
- ◆ **ias\_ContentType** The type of message:

<code>IAS_TEXT_CONTENT</code>	The message content consists of unicode characters.
<code>IAS_BINARY_CONTENT</code>	The message content is treated as an uninterpreted sequence of bytes.

- ◆ **ias\_Expires** The date and time when the message will expire if it is not delivered.

- ◆ **ias\_Priority** The priority of message: an integer between 0 and 9, where 0 indicates less priority and 9 indicates more priority.
- ◆ **ias\_TransmissionStatus** The synchronization status of the message. It can be one of:

IAS_UNTRANSMITTED	The message has not been transmitted to its intended recipient message store.
IAS_TRANSMITTED	The message has been transmitted to its intended recipient message store.
IAS_DO_NOT_TRANSMIT	The recipient and originating message stores are the same so no transmission is necessary.
IAS_TRANSMITTING	The message has been transmitted to its intended recipient, but that transmission has yet to be confirmed. There is a possibility that the message transmission was interrupted, and that QAnywhere may transmit the message again.

## Status constants defined by the rule engine

- ◆ **ias\_CurrentDate** The current date.  
A string can be compared against `ias_currentDate` if it is supplied in one of two ways:
  - ◆ as a string of format, which is interpreted unambiguously.
  - ◆ as a string according to the `date_format` database option set for the client message store database.

For more information, see [“Setting options” \[SQL Anywhere Server - Database Administration\]](#) and [“date\\_format option \[compatibility\]” \[SQL Anywhere Server - Database Administration\]](#).
- ◆ **ias\_Status** The current status of the message. The values can be:
  - ◆ **ias\_CancelledState** The message has been cancelled.
  - ◆ **ias\_ExpiredState** The message expired before it could be received by the intended recipient.
  - ◆ **ias\_FinalState** The message is received or expired. Therefore, `>=ias_FinalState` means that the message is received or expired, and `<ias_FinalState` means that the message is neither received nor expired.
  - ◆ **ias\_PendingState** The message has not yet been received by the intended recipient.
  - ◆ **ias\_ReceivedState** The message was received by the intended recipient.
  - ◆ **ias\_UnreceivableState** The message has been marked as unreceivable because it is either malformed or there were too many failed attempts to deliver it.
- ◆ **ias\_Network** Information about the current network in use. `ias_Network` is a special transmission variable. It has a number of built-in attributes that provide information regarding the current network that is being used by the device.

- ◆ **ias\_CurrentTime** The current time.

A string can be compared against `ias_CurrentTime` if the hours, minutes, and seconds are separated by colons in the format `hh:mm:ss:sss`. A 24-hour clock is assumed unless **am** or **pm** is specified. See [“time\\_format option \[compatibility\]” \[SQL Anywhere Server - Database Administration\]](#).

- ◆ **ias\_CurrentTimestamp** The current timestamp (current date and time). See [“time\\_format option \[compatibility\]” \[SQL Anywhere Server - Database Administration\]](#).

### Example

For an example of how to create client store properties and use them in transmission rules, see [“Using custom client message store property attributes” on page 217](#).

## Message transmission rules

Message transmission is the action of moving messages from a client message store to a server message store, or vice versa.

Message transmission is handled by the QAnywhere Agent and the MobiLink server:

- ◆ The QAnywhere Agent is connected to the client message store. It transmits messages to and from the MobiLink server.
- ◆ The MobiLink server is connected to the server message store. It receives message transmissions from QAnywhere Agents and transmits them to other QAnywhere Agents.

Message transmission can only take place between a client message store and a server message store. A message transmission can only occur when a QAnywhere Agent is connected to a MobiLink server.

Transmission rules allow you to specify when message transmission is to occur and which messages to transmit. Delete rules allow you to specify when messages should be deleted from the message stores, if you do not want to use the default behavior.

You can specify transmission rules on the server and on the client. For more information, see:

- ◆ [“Client transmission rules” on page 234](#)
- ◆ [“Server transmission rules” on page 235](#)

## Client transmission rules

Client transmission rules govern the behavior of messages going from the client to the server. Client transmission rules are handled by the QAnywhere Agent.

By default, the QAnywhere Agent uses the automatic policy. You can change and customize this behavior by specifying a transmission rules file as the transmission policy for the QAnywhere Agent.

The following partial qaagent command line shows how to specify a rules file for the QAnywhere Agent:

```
qaagent -policy myrules.txt ...
```

 For a complete description of how to write transmission rules, see [“Rule syntax” on page 226](#).

 For more information about policies, see:

- ◆ [“Determining when message transmission should occur on the client” on page 36](#)
- ◆ [“-policy option” on page 163](#)

 For information about client delete rules, see [“Client delete rules” on page 239](#).

The transmission rules file holds the following kinds of entry:

- ◆ **Rules** No more than one rule can be entered per line.

Each rule must be entered on a single line, but you can use \ as a line continuation character.

- ◆ **Comments** Comments are indicated by a line beginning with either a # or ; character. Any characters on that line are ignored.

☞ For more information, see [“Rule syntax” on page 226](#) and [“Condition syntax” on page 228](#).

You can also use transmission rules files to determine when messages are to be deleted from the message stores.

☞ For more information, see [“Message delete rules” on page 239](#).

You can also use the Sybase Central QAnywhere plug-in to create a QAnywhere Agent rules file.

### Example

For example, the following client transmission rules file specifies that during business hours only small high priority messages should be transmitted, while outside of business hours, any message can be transmitted. This rule is automatic, which indicates that if the condition is satisfied, the message is transmitted immediately. This example demonstrates that conditions can use information derived from the message as well as other information such as the current time.

```
automatic = ( ias_ContentSize < 100000 and ias_Priority > 7 ) \
             or datepart(Weekday,Ias_CurrentDate) in ( 1, 7 ) \
             or ias_CurrentTime < '8:00:00' or ias_CurrentTime > '18:00:00'
```

## Server transmission rules

Server transmission rules govern the behavior of messages going from the server to the client. Server transmission rules are handled by the MobiLink server. They apply both when you are using push notifications and when you are not using notifications.

There are several ways to set server transmission rules:

- ◆ Write a server management request to set the transmission rule.  
See [“Specifying transmission rules with a server management request” on page 116](#).
- ◆ Use Sybase Central to set the rules.  
See [“Specifying server transmission rules using Sybase Central” on page 236](#).
- ◆ Create a server transmission rules file and specify it when you start the MobiLink server. This method is deprecated.  
See [“Specifying server transmission rules with a transmission rules file \(deprecated\)” on page 236](#).

### Setting default rules

You can specify server transmission rules for a particular message store or destination alias, or you can set default rules for all clients. Every user that does not have an explicit transmission rule will use the default rule.

To set default rules, you use the special client name `ianywhere.server.defaultClient`.

### Specifying server transmission rules using Sybase Central

You can create and edit transmission rules in Sybase Central.

#### ◆ To specify default server transmission rules

1. Start Sybase Central:
  - ◆ Choose Start ► Programs ► SQL Anywhere 10 ► Sybase Central.
  - ◆ From Connections, choose Connect with QAnywhere 10.
  - ◆ Specify an ODBC data source name or file, and a user ID and password if required. Click OK.
2. From Server Store Tasks, click Change Properties of this Message Store.  
The Properties dialog appears.
3. Open the Transmission Rules tab and select Customize the Default Transmission Rules.
4. Click New to add a rule.  
The Rule Editor appears.
5. Add conditions either by typing them into the text field or by choosing Message Variables or Status Constants from the drop-down lists.
6. Click OK to exit.

### Specifying server transmission rules with a transmission rules file (deprecated)

You can create a server transmission rules file and specify it with the `ianywhere.qa.server.transmissionRulesFile` property in your QAnywhere messaging properties file.

 For more information about the messaging properties file, see “-m option” [[MobiLink - Server Administration](#)].

To specify transmission rules for a particular client, precede a section of rules with the client message store ID in square brackets.

Default server transmission rules can be created that apply to all users.

To specify default transmission rules, start a section with the following line:

```
[ianywhere.server.defaultClient]
```

For new transmission rules to take effect, you must restart the MobiLink server. This only applies to transmission rules specified in a transmission rules file. Server transmission rules specified using Sybase Central or a server management request take effect immediately.

☞ For information about server delete rules, see [“Server delete rules” on page 239](#).

### Example

The following section of a server transmission rules file creates the default rule that only high priority messages should be sent:

```
[ianywhere.server.defaultClient]
auto = ias_Priority > 6
```

In the following sample server transmission rules file, the rules apply only to the client identified by the client message store ID `sample_store_id`.

```
[sample_store_id]
; This rule governs when messages are transmitted to the client
; store with id sample_store_id.
;
;   ias_Priority >= 7
;
; Messages with priority 7 or greater should always be
; transmitted.
;
;   ias_ContentSize < 100
;
; Small messages (messages less than 100 characters or
; bytes in size) should always be transmitted.
;
;   ias_CurrentTime < '8:00am' or ias_CurrentTime > '6:00pm'
;
; Outside of business hours messages should always be
; transmitted

auto = ias_Priority >= 7 or ias_ContentSize < 100 \
      or ias_CurrentTime < '8:00:00' or ias_CurrentTime > '18:00:00'
```

In the following example, the rules apply only to the client identified by the client message store ID `qanywhere`.

```
[qanywhere]
; This rule governs when messages are transmitted to the client
; store with id qanywhere.
;
;   tm_Subject not like '%non-business%'
;
; Messages with the property tm_Subject set to a value that
; includes the phrase 'non-business' should not be transmitted
;
;   ias_CurrentTime < '8:00:00' or ias_CurrentTime > '18:00:00'
;
; Outside of business hours, messages should always be
; transmitted
```

```
auto = tm_Subject not like '%non-business%' \  
      or ias_CurrentTime < '8:00am' or ias_CurrentTime > '6:00pm'
```

## Message delete rules

Delete rules determine the persistence of messages in the client message store and the server message store.

### Client delete rules

By default, messages are deleted from the client message store when the status of the message is determined to be received, expired, cancelled, or undeliverable and the final state has been transmitted to the server message store. You may want messages to be deleted faster than that, or to hold on to messages longer. You do that by creating a delete section in your client transmission rules file. The delete section must be prefaced by **[system:delete]**.

For more information about acknowledgement, see:

- ◆ .NET: [“AcknowledgementMode enumeration” on page 244](#)
- ◆ C++: [“AcknowledgementMode class” on page 392](#)
- ◆ Java: [“Interface AcknowledgementMode” on page 504](#)

☞ For more information about client transmission rules, see [“Client transmission rules” on page 234](#).

Following is an example of the delete rules section in a client transmission rules file:

```
[system:delete]

; This rule governs when messages are deleted from the client
; store.
;
;   start time '1:00:00' on ( 'Sunday' )
;
; Messages are deleted every Sunday at 1:00 A.M.
;
;   ias_Status >= ias_FinalState
;
; Typically, messages are deleted when they reach a final
; state: received, unreceivable, expired, or cancelled.

start time '1:00:00' on ( 'Sunday' ) = ias_Status >= ias_FinalState
```

☞ For an explanation of `ias_Status`, see [“Rule variables” on page 231](#).

### Server delete rules

By default, messages are deleted from the server message store when the status of the message is determined to be received, expired, cancelled, or undeliverable and the final state has been transmitted back to the message originator. You may want to keep messages longer for purposes such as auditing.

Server-side delete rules apply to all messages in the server message store.

☞ For more information about server transmission rules, see [“Server transmission rules” on page 235](#).

☞ For an explanation of `ias_Status`, see [“Rule variables” on page 231](#).

---

## **Part II. QAnywhere API Reference**

This part provides reference documentation of the QAnywhere APIs.

---

CHAPTER 12

## QAnywhere .NET API Reference

### Contents

iAnywhere.QAnywhere.Client namespace (.NET ) .....	244
iAnywhere.QAnywhere.WS namespace (.NET ) .....	342

#### About this chapter

The iAnywhere.QAnywhere.Client namespace contains classes and enumerations for building applications that handle QAnywhere messages.

## iAnywhere.QAnywhere.Client namespace (.NET )

### AcknowledgementMode enumeration

Indicates how messages should be acknowledged by QAnywhere client applications.

#### Prototypes

```
' Visual Basic  
Public Enum AcknowledgementMode
```

```
// C#  
public enum AcknowledgementMode
```

#### Remarks

The implicit and explicit acknowledgement modes are assigned to a QAManager instance using the [Open method](#).

For more information, see [“Initializing a QAnywhere API” on page 54](#).

With implicit acknowledgement, messages are acknowledged as soon as they are received by a client application. With explicit acknowledgement, you must call one of the QAManager acknowledgement methods. The server propagates all status changes from client to client.

For more information, see [“Receiving messages synchronously” on page 75](#) and [“Receiving messages asynchronously” on page 76](#).

#### Member name

Member name	Description
EXPLICIT_ACKNOWLEDGEMENT	Indicates that received messages are acknowledged using one of the <a href="#">QAManager interface</a> acknowledge methods.
IMPLICIT_ACKNOWLEDGEMENT	Indicates that all messages are acknowledged as soon as they are received by a client application. If you receive messages synchronously, messages are acknowledged as soon as the <a href="#">GetMessage method</a> returns. If you receive messages asynchronously, the message is acknowledged as soon as the event handling function returns.
TRANSACTIONAL	This mode indicates that messages are only acknowledged as part of the on going transaction. This mode is automatically assigned to <a href="#">QA-TransactionalManager interface</a> instances.

#### See also

- ◆ [“QAManager interface” on page 271](#)
- ◆ [“QATransactionalManager interface” on page 337](#)
- ◆ [“QAManagerBase interface” on page 275](#)

## MessageListener delegate

MessageListener delegate definition. You pass a MessageListener to the [SetMessageListener method](#).

### Prototypes

```
' Visual Basic
Public Delegate Sub MessageListener( _
    ByVal msg As QAMessage _
)

// C#
public delegate void MessageListener(
    QAMessage msg
);
```

### Parameters

- ◆ **msg** The message that was received.

## MessageProperties class

Provides fields storing standard message property names.

### Prototypes

```
' Visual Basic
Public Class MessageProperties

// C#
public class MessageProperties
```

### Remarks

The MessageProperties class provides standard message property names. You can pass MessageProperties fields to QAMessage methods used to get and set message properties.

For more information, see [“Message headers and message properties” on page 206](#).

### See also

- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“QAMessage interface” on page 314](#)

## MessageProperties members

### Public static fields (shared)

Member name	Description
<a href="#">ADAPTER field</a>	For "system" queue messages, the network adapter that is being used to connect to the QAnywhere server.

Member name	Description
<a href="#">ADAPTERS field</a>	This property name refers to a delimited list of network adapters that can be used to connect to the QAnywhere server.
<a href="#">DELIVERY_COUNT field</a>	This property name refers to the number of attempts that have been made so far to deliver the message.
<a href="#">IP field</a>	For "system" queue messages, the IP address of the network adapter that is being used to connect to the QAnywhere server.
<a href="#">MAC field</a>	For "system" queue messages, the MAC address of the network adapter that is being used to connect to the QAnywhere server.
<a href="#">MSG_TYPE field</a>	This property name refers to <a href="#">MessageType enumeration</a> values associated with a QAnywhere message.
<a href="#">NETWORK_STATUS field</a>	This property name refers to the state of the network connection.
<a href="#">ORIGINATOR field</a>	This property name refers to the message store ID of the originator of the message.
<a href="#">RAS field</a>	For "system" queue messages, the RAS entry name that is being used to connect to the QAnywhere server.
<a href="#">RASNAMES field</a>	For "system" queue messages, a delimited list of RAS entry names that can be used to connect to the QAnywhere server.
<a href="#">STATUS field</a>	This property name refers to the current status of the message.
<a href="#">STATUS_TIME field</a>	This property name refers to the time at which the message became its current status.
<a href="#">TRANSMISSION_STATUS field</a>	This property name refers to the current transmission status of the message.

### ADAPTER field

For "system" queue messages, the network adapter that is being used to connect to the QAnywhere server.

### Prototypes

```
' Visual Basic
Public Shared ADAPTER As String
```

```
// C#
public const string ADAPTER;
```

### Remarks

The value of this field is "ias\_Network.Adapter".

For more information, see [“Pre-defined client message store properties” on page 215](#).

You can pass `MessageProperties.ADAPTER` in the [QAMessage interface GetStringProperty method](#) to access the associated property.

### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

## ADAPTERS field

This property name refers to a delimited list of network adapters that can be used to connect to the QAnywhere server.

### Prototypes

```
' Visual Basic  
Public Shared ADAPTERS As String
```

```
// C#  
public const string ADAPTERS;
```

### Remarks

It is used for system queue messages.

You can pass `MessageProperties.ADAPTERS` in the [QAMessage interface GetStringProperty method](#) to access the associated property.

For more information, see [“Pre-defined client message store properties” on page 215](#).

### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

## DELIVERY\_COUNT field

This property name refers to the number of attempts that have been made so far to deliver the message.

### Prototypes

```
' Visual Basic  
Public Shared DELIVERY_COUNT As String
```

```
// C#  
public const string DELIVERY_COUNT;
```

### Remarks

The value of this field is `"ias_DeliveryCount"`.

You can pass `MessageProperties.DELIVERY_COUNT` in the [QAMessage interfaceGetIntProperty method](#) to access the associated property.

### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

### IP field

For "system" queue messages, the IP address of the network adapter that is being used to connect to the QAnywhere server.

### Prototypes

```
' Visual Basic
Public Shared IP As String
```

```
// C#
public const string IP;
```

### Remarks

The value of this field is "ias\_Network.IP".

For more information, see [“Pre-defined client message store properties” on page 215](#).

You can pass `MessageProperties.IP` in the [QAMessage interfaceGetStringProperty method](#) to access the associated property.

### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

### MAC field

For "system" queue messages, the MAC address of the network adapter that is being used to connect to the QAnywhere server.

### Prototypes

```
' Visual Basic
Public Shared MAC As String
```

```
// C#
public const string MAC;
```

### Remarks

The value of this field is "ias\_Network.MAC".

For more information, see [“Pre-defined client message store properties” on page 215](#).

You can pass `MessageProperties.MAC` in the [QAMessage interfaceGetStringProperty method](#) to access the associated property.

#### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

### MSG\_TYPE field

This property name refers to [MessageType enumeration](#) values associated with a QAnywhere message.

#### Prototypes

```
' Visual Basic  
Public Shared MSG_TYPE As String
```

```
// C#  
public const string MSG_TYPE;
```

#### Remarks

The value of this field is "ias\_MessageType".

You can pass `MessageProperties.MSG_TYPE` in the [QAMessage interfaceGetIntProperty method](#) to access the associated property.

#### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

### NETWORK\_STATUS field

This property name refers to the state of the network connection.

#### Prototypes

```
' Visual Basic  
Public Shared NETWORK_STATUS As String
```

```
// C#  
public const string NETWORK_STATUS;
```

#### Remarks

The value is 1 if the network is accessible and 0 otherwise.

The network status is used for system queue messages (for example, network status changes).

For more information, see [“Pre-defined client message store properties” on page 215](#).

You can pass `MessageProperties.NETWORK_STATUS` in the [QAMessage interfaceGetIntProperty method](#) to access the associated property.

#### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

## ORIGINATOR field

This property name refers to the message store ID of the originator of the message.

#### Prototypes

```
' Visual Basic  
Public Shared ORIGINATOR As String
```

```
// C#  
public const string ORIGINATOR;
```

#### Remarks

The value of this field is "ias\_Originator".

You can pass `MessageProperties.ORIGINATOR` in the [QAMessage interfaceGetStringProperty method](#) to access the associated property.

#### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

## RAS field

For "system" queue messages, the RAS entry name that is being used to connect to the QAnywhere server.

#### Prototypes

```
' Visual Basic  
Public Shared RAS As String
```

```
// C#  
public const string RAS;
```

#### Remarks

The value of this field is "ias\_Network.RAS".

For more information, see [“Pre-defined client message store properties” on page 215](#).

You can pass `MessageProperties.RAS` in the [QAMessage interfaceGetStringProperty method](#) to access the associated property.

### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

## RASNAMES field

For "system" queue messages, a delimited list of RAS entry names that can be used to connect to the QAnywhere server.

### Prototypes

```
' Visual Basic
Public Shared RASNAMES As String
```

```
// C#
public const string RASNAMES;
```

### Remarks

The value of this field is "ias\_RASNames".

For more information, see [“Pre-defined client message store properties” on page 215](#).

You can pass `MessageProperties.RASNAMES` in the [QAMessage interfaceGetStringProperty method](#) to access the associated property.

### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“MessageProperties class” on page 245](#)

## STATUS field

This property name refers to the current status of the message.

### Prototypes

```
' Visual Basic
Public Shared STATUS As String
```

```
// C#
public const string STATUS;
```

### Remarks

For a list of property values, see the [StatusCodes enumeration](#) class.

The value of this field is "ias\_Status".

You can pass `MessageProperties.STATUS` in the [QAMessage interface GetIntProperty method](#) to access the associated property.

#### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“StatusCodes enumeration” on page 340](#)
- ◆ [“MessageProperties class” on page 245](#)

### STATUS\_TIME field

This property name refers to the time at which the message became its current status.

#### Prototypes

```
' Visual Basic  
Public Shared STATUS_TIME As String
```

```
// C#  
public const string STATUS_TIME;
```

#### Remarks

It is a local time. When `STATUS_TIME` is passed to [GetProperty method](#), it returns a `DateTime` object. The value of this field is "ias\_StatusTime".

#### See also

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“GetProperty method” on page 324](#)
- ◆ [“MessageProperties class” on page 245](#)

### TRANSMISSION\_STATUS field

This property name refers to the current transmission status of the message.

#### Prototypes

```
' Visual Basic  
Public Shared TRANSMISSION_STATUS As String
```

```
// C#  
public const string TRANSMISSION_STATUS;
```

#### Remarks

For a list of property values, see the [StatusCodes enumeration](#) class.

The value of this field is "ias\_TransmissionStatus".

You can pass `MessageProperties.TRANSMISSION_STATUS` in the [QAMessage interface GetIntProperty method](#) to access the associated property.

**See also**

- ◆ [“MessageProperties class” on page 245](#)
- ◆ [“MessageProperties members” on page 245](#)
- ◆ [“StatusCodes enumeration” on page 340](#)
- ◆ [“MessageProperties class” on page 245](#)

**MessageStoreProperties class**

This class defines constant values for useful message store property names. The `MessageStoreProperties` class provides standard message property names. You can pass `MessageProperties` fields to `QAManagerBase` methods used to get and set pre-defined or custom message store properties. For more information, see [“Client message store properties” on page 215](#).

**Prototypes**

**' Visual Basic**  
Public Class `MessageStoreProperties`

**// C#**  
public class `MessageStoreProperties`

**MessageStoreProperties members****Public static fields (shared)**

Member name	Description
<a href="#">MAX_DELIVERY_ATTEMPTS</a> field	This property name refers to the maximum number of times that a message can be received, without explicit acknowledgement, before its status is set to <a href="#">StatusCodes enumeration.UNRECEIVABLE</a> . The value of this field is "ias_MaxDeliveryAttempts".

**Public constructors**

Member name	Description
<a href="#">MessageStoreProperties</a> constructor	Initializes a new instance of the <a href="#">MessageStoreProperties class</a> class.

**MessageStoreProperties constructor**

Initializes a new instance of the [MessageStoreProperties class](#) class.

**Prototypes**

**' Visual Basic**  
Public Sub `New()`

```
// C#
public MessageStoreProperties();
```

### MAX\_DELIVERY\_ATTEMPTS field

This property name refers to the maximum number of times that a message can be received, without explicit acknowledgement, before its status is set to [StatusCodes enumeration.UNRECEIVABLE](#). The value of this field is "ias\_MaxDeliveryAttempts".

#### Prototypes

```
' Visual Basic
Public Shared MAX_DELIVERY_ATTEMPTS As String
```

```
// C#
public const string MAX_DELIVERY_ATTEMPTS;
```

### MessageType enumeration

Defines constant values for the [MessageProperties class.MSG\\_TYPE](#) message property.

#### Prototypes

```
' Visual Basic
Public Enum MessageType
```

```
// C#
public enum MessageType
```

#### Member name

Member name	Description
NETWORK_STATUS_NOTIFICATION	Identifies a QAnywhere system message used to notify QAnywhere client applications of network status changes.
PUSH_NOTIFICATION	Identifies a QAnywhere system message used to notify QAnywhere client applications of push notifications.
REGULAR	If no message type property exists then the message type is assumed to be REGULAR.

### PropertyType enumeration

QAMessage property type enumeration, corresponding naturally to the C# types.

#### Prototypes

```
' Visual Basic
Public Enum PropertyType
```

```
// C#
public enum PropertyType
```

#### Member name

Member name	Description
BOOLEAN	Indicates a boolean property.
BYTE	Indicates a signed byte property.
DOUBLE	Indicates a double property.
FLOAT	Indicates a float property.
INT	Indicates an int property.
LONG	Indicates an long property.
SHORT	Indicates a short property.
STRING	Indicates a string property.
UNKNOWN	Indicates an unknown property type, usually because the property is unknown.

## QABinaryMessage interface

An QABinaryMessage object is used to send a message containing a stream of uninterpreted bytes. It inherits from the [QAMessage interface](#) class and adds a bytes message body. QABinaryMessage provides a variety of functions to read from and write to the bytes message body.

When the message is first created, the body of the message is in write-only mode. After a message has been sent, the client that sent it can retain and modify it without affecting the message that has been sent. The same message object can be sent multiple times.

When a message is received, the provider has called [Reset method](#) so that the message body is in read-only mode and reading of values starts from the beginning of the message body.

### Prototypes

```
' Visual Basic
Public Interface QABinaryMessage
```

```
// C#
public interface QABinaryMessage
```

## QABinaryMessage members

### Public properties

Member name	Description
<a href="#">BodyLength property</a>	Returns the size of the message body in bytes.

### Public methods

Member name	Description
<a href="#">ReadBinary method</a>	Reads a specified number of bytes starting from the unread portion of a QABinaryMessage instance body.
<a href="#">ReadBoolean method</a>	Reads a boolean value starting from the unread portion of the QABinaryMessage instance's message body.
<a href="#">ReadChar method</a>	Reads a char value starting from the unread portion of a QABinaryMessage message body.
<a href="#">ReadDouble method</a>	Reads a double value starting from the unread portion of a QABinaryMessage message body.
<a href="#">ReadFloat method</a>	Reads a float value starting from the unread portion of a QABinaryMessage message body.
<a href="#">ReadInt method</a>	Reads an integer value starting from the unread portion of a QABinaryMessage message body.
<a href="#">ReadLong method</a>	Reads a long value starting from the unread portion of a QABinaryMessage message body.
<a href="#">ReadSbyte method</a>	Reads a signed byte value starting from the unread portion of a QABinaryMessage message body.
<a href="#">ReadShort method</a>	Reads a short value starting from the unread portion of a QABinaryMessage message body.
<a href="#">ReadString method</a>	Reads a string value starting from the unread portion of a QABinaryMessage message body.
<a href="#">Reset method</a>	Resets a message so that the reading of values starts from the beginning of the message body. The Reset method also puts the QABinaryMessage message body in read-only mode.
<a href="#">WriteBinary method</a>	Appends a byte array value to the QABinaryMessage instance's message body.
<a href="#">WriteBoolean method</a>	Appends a boolean value to the QABinaryMessage instance's message body. The boolean is represented as a one byte value. True is represented as 1; false is represented as 0.

Member name	Description
<a href="#">WriteChar method</a>	Appends a char value to the QABinaryMessage instance's message body. The char is represented as a two byte value and the high order byte is appended first.
<a href="#">WriteDouble method</a>	Appends a double value to the QABinaryMessage instance's message body. The double is converted to a representative 8-byte long and higher order bytes are appended first.
<a href="#">WriteFloat method</a>	Appends a float value to the QABinaryMessage instance's message body. The float parameter is converted to a representative 4-byte integer and the higher order bytes are appended first.
<a href="#">WriteInt method</a>	Appends an integer value to the QABinaryMessage instance's message body. The integer parameter is represented as a 4 byte value and higher order bytes are appended first.
<a href="#">WriteLong method</a>	Appends a long value to the QABinaryMessage instance's message body. The long parameter is represented using 8-bytes value and higher order bytes are appended first.
<a href="#">WriteSbyte method</a>	Appends a signed byte value to the QABinaryMessage instance's message body. The signed byte is represented as a one byte value.
<a href="#">WriteShort method</a>	Appends a short value to the QABinaryMessage instance's message body. The short parameter is represented as a two byte value and the higher order byte is appended first.
<a href="#">WriteString method</a>	Appends a string value to the QABinaryMessage instance's message body. Note: the receiving application needs to invoke <a href="#">ReadString method</a> for each WriteString invocation. Note: The UTF-8 representation of the string to be written can be at most 32767 bytes.

## BodyLength property

Returns the size of the message body in bytes.

### Prototypes

**Visual Basic**  
Public Readonly Property **BodyLength** As Long

**C#**  
public long **BodyLength** {get;}

### See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)

## ReadBinary method

Reads a specified number of bytes starting from the unread portion of a QABinaryMessage instance body.

### Prototypes

```
' Visual Basic
Public Function ReadBinary( _
    ByVal bytes As Byte(), _
    ByVal len As Integer _
) As Integer
```

```
// C#
public int ReadBinary(
    byte[] bytes,
    int len
);
```

### Parameters

- ◆ **bytes** the byte array that will contain the read bytes.
- ◆ **len** the maximum number of bytes to read

### Return value

the number of bytes read from the message body.

### Exceptions

- ◆ [QAException class](#) - if there was a conversion error reading the value or if there is no more input.

### See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteBinary method” on page 263](#)

## ReadBoolean method

Reads a boolean value starting from the unread portion of the QABinaryMessage instance's message body.

### Prototypes

```
' Visual Basic
Public Function ReadBoolean() As Boolean
```

```
// C#
public bool ReadBoolean();
```

### Return value

the boolean value read from the message body.

## Exceptions

- ◆ [QAException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteBoolean method” on page 264](#)

## ReadChar method

Reads a char value starting from the unread portion of a QABinaryMessage message body.

## Prototypes

**' Visual Basic**  
Public Function **ReadChar()** As Char

**// C#**  
public char **ReadChar();**

## Return value

the character value read from the message body.

## Exceptions

- ◆ [QAException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteChar method” on page 264](#)

## ReadDouble method

Reads a double value starting from the unread portion of a QABinaryMessage message body.

## Prototypes

**' Visual Basic**  
Public Function **ReadDouble()** As Double

**// C#**  
public double **ReadDouble();**

## Return value

the double value read from the message body.

## Exceptions

- ◆ [QException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteDouble method” on page 265](#)

## ReadFloat method

Reads a float value starting from the unread portion of a QABinaryMessage message body.

## Prototypes

```
' Visual Basic  
Public Function ReadFloat() As Single
```

```
// C#  
public float ReadFloat();
```

## Return value

the float value read from the message body.

## Exceptions

- ◆ [QException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteFloat method” on page 265](#)

## ReadInt method

Reads an integer value starting from the unread portion of a QABinaryMessage message body.

## Prototypes

```
' Visual Basic  
Public Function ReadInt() As Integer
```

```
// C#  
public int ReadInt();
```

## Return value

the int value read from the message body.

## Exceptions

- ◆ [QAException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteInt method” on page 266](#)

## ReadLong method

Reads a long value starting from the unread portion of a QABinaryMessage message body.

## Prototypes

```
' Visual Basic  
Public Function ReadLong() As Long
```

```
// C#  
public long ReadLong();
```

## Return value

the long value read from the message body.

## Exceptions

- ◆ [QAException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteLong method” on page 266](#)

## ReadSbyte method

Reads a signed byte value starting from the unread portion of a QABinaryMessage message body.

## Prototypes

```
' Visual Basic  
Public Function ReadSbyte() As System.SByte
```

```
// C#  
public System.Sbyte ReadSbyte();
```

## Return value

the signed byte value read from the message body.

## Exceptions

- ◆ [QException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteSbyte method” on page 267](#)

## ReadShort method

Reads a short value starting from the unread portion of a QABinaryMessage message body.

### Prototypes

```
' Visual Basic  
Public Function ReadShort() As Short
```

```
// C#  
public short ReadShort();
```

### Return value

the short value read from the message body.

### Exceptions

- ◆ [QException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteShort method” on page 267](#)

## ReadString method

Reads a string value starting from the unread portion of a QABinaryMessage message body.

### Prototypes

```
' Visual Basic  
Public Function ReadString() As String
```

```
// C#  
public string ReadString();
```

### Return value

the string value read from the message body.

## Exceptions

- ◆ [QException class](#) - if there was a conversion error reading the value or if there is no more input.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“WriteString method” on page 268](#)

## Reset method

Resets a message so that the reading of values starts from the beginning of the message body. The Reset method also puts the QABinaryMessage message body in read-only mode.

## Prototypes

```
' Visual Basic
Public Sub Reset()
```

```
// C#
public void Reset();
```

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)

## WriteBinary method

Appends a byte array value to the QABinaryMessage instance's message body.

## Prototypes

```
' Visual Basic
Public Sub WriteBinary( _
    ByVal val As Byte(), _
    ByVal offset As Integer, _
    ByVal len As Integer _
)
```

```
// C#
public void WriteBinary(
    byte[] val,
    int offset,
    int len
);
```

## Parameters

- ◆ **val** the byte array value to write to the message body.

- ◆ **len** the number of bytes to write.
- ◆ **offset** the offset within the byte array to begin writing.

**See also**

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadBinary method” on page 258](#)

**WriteBoolean method**

Appends a boolean value to the QABinaryMessage instance's message body. The boolean is represented as a one byte value. True is represented as 1; false is represented as 0.

**Prototypes**

```
' Visual Basic
Public Sub WriteBoolean( _
    ByVal val As Boolean _
)

// C#
public void WriteBoolean(
    bool val
);
```

**Parameters**

- ◆ **val** the boolean value to write to the message body.

**See also**

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadBoolean method” on page 258](#)

**WriteChar method**

Appends a char value to the QABinaryMessage instance's message body. The char is represented as a two byte value and the high order byte is appended first.

**Prototypes**

```
' Visual Basic
Public Sub WriteChar( _
    ByVal val As Char _
)

// C#
public void WriteChar(
```

```
char val  
);
```

### Parameters

- ◆ **val** the char value to write to the message body.

### See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadChar method” on page 259](#)

## WriteDouble method

Appends a double value to the QABinaryMessage instance's message body. The double is converted to a representative 8-byte long and higher order bytes are appended first.

### Prototypes

```
' Visual Basic  
Public Sub WriteDouble( _  
    ByVal val As Double _  
)  
  
// C#  
public void WriteDouble(  
    double val  
);
```

### Parameters

- ◆ **val** the double value to write to the message body.

### See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadDouble method” on page 259](#)

## WriteFloat method

Appends a float value to the QABinaryMessage instance's message body. The float parameter is converted to a representative 4-byte integer and the higher order bytes are appended first.

### Prototypes

```
' Visual Basic  
Public Sub WriteFloat( _  
    ByVal val As Single _  
)
```

```
// C#  
public void WriteFloat(  
    float val  
);
```

### Parameters

- ◆ **val** the float value to write to the message body.

### See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadFloat method” on page 260](#)

## WriteInt method

Appends an integer value to the QABinaryMessage instance's message body. The integer parameter is represented as a 4 byte value and higher order bytes are appended first.

### Prototypes

```
' Visual Basic  
Public Sub WriteInt(  
    ByVal val As Integer _  
)  
  
// C#  
public void WriteInt(  
    int val  
);
```

### Parameters

- ◆ **val** the int value to write to the message body.

### See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadInt method” on page 260](#)

## WriteLong method

Appends a long value to the QABinaryMessage instance's message body. The long parameter is represented using 8-bytes value and higher order bytes are appended first.

### Prototypes

```
' Visual Basic  
Public Sub WriteLong( _
```

```
    ByVal val As Long _  
)  
  
// C#  
public void WriteLong(  
    long val  
);
```

### Parameters

- ◆ **val** the long value to write to the message body.

### See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadLong method” on page 261](#)

## WriteSbyte method

Appends a signed byte value to the QABinaryMessage instance's message body. The signed byte is represented as a one byte value.

### Prototypes

```
' Visual Basic  
Public Sub WriteSbyte(  
    ByVal val As System.SByte _  
)  
  
// C#  
public void WriteSbyte(  
    System.Sbyte val  
);
```

### Parameters

- ◆ **val** the signed byte value to write to the message body.

### See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadSbyte method” on page 261](#)

## WriteShort method

Appends a short value to the QABinaryMessage instance's message body. The short parameter is represented as a two byte value and the higher order byte is appended first.

## Prototypes

```
' Visual Basic
Public Sub WriteShort( _
    ByVal val As Short _
)

// C#
public void WriteShort(
    short val
);
```

## Parameters

- ◆ **val** the short value to write to the message body.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadShort method” on page 262](#)

## WriteString method

Appends a string value to the QABinaryMessage instance's message body. Note: the receiving application needs to invoke [ReadString method](#) for each WriteString invocation. Note: The UTF-8 representation of the string to be written can be at most 32767 bytes.

## Prototypes

```
' Visual Basic
Public Sub WriteString( _
    ByVal val As String _
)

// C#
public void WriteString(
    string val
);
```

## Parameters

- ◆ **val** the string value to write to the message body.

## See also

- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“QABinaryMessage members” on page 256](#)
- ◆ [“QABinaryMessage interface” on page 255](#)
- ◆ [“ReadString method” on page 262](#)

## QAException class

Encapsulates QAnywhere client application exceptions. You can use the QAException class to catch QAnywhere exceptions.

### Prototypes

**' Visual Basic**  
Public Class **QAException**  
Inherits ApplicationException

**// C#**  
public class **QAException** :  
ApplicationException

## QAException members

### Public constructors

Member name	Description
<a href="#">QAException constructor</a>	Create a QAException instance providing the error message text.
<a href="#">QAException constructor</a>	Create a QAException instance providing the error code and the error message text.

### Public properties

Member name	Description
<a href="#">ErrorCode property</a>	The error code of the exception.
<a href="#">HelpLink</a> (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
<a href="#">InnerException</a> (inherited from Exception)	Gets the <a href="#">System.Exception</a> instance that caused the current exception.
<a href="#">Message</a> (inherited from Exception)	Gets a message that describes the current exception.
<a href="#">Source</a> (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
<a href="#">StackTrace</a> (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
<a href="#">TargetSite</a> (inherited from Exception)	Gets the method that throws the current exception.

**Public methods**

Member name	Description
<a href="#">GetBaseException</a> (inherited from <a href="#">Exception</a> )	When overridden in a derived class, returns the <a href="#">System.Exception</a> that is the root cause of one or more subsequent exceptions.
<a href="#">GetObjectData</a> (inherited from <a href="#">Exception</a> )	When overridden in a derived class, sets the <a href="#">System.Runtime.Serialization.SerializationInfo</a> with information about the exception.
<a href="#">ToString</a> (inherited from <a href="#">Exception</a> )	Creates and returns a string representation of the current exception.

**QAException constructor**

Create a QAException instance providing the error message text.

**Prototypes**

```
' Visual Basic
Overloads Public Sub New( _
    ByVal msg As String _
)

// C#
public QAException(
    string msg
);
```

**Parameters**

- ◆ **msg** the text description of the exception.

**QAException constructor**

Create a QAException instance providing the error code and the error message text.

**Prototypes**

```
' Visual Basic
Overloads Public Sub New( _
    ByVal msg As String, _
    ByVal errCode As Integer _
)

// C#
public QAException(
    string msg,
    int errCode
);
```

**Parameters**

- ◆ **msg** the text description of the exception.
- ◆ **errCode** the error code.

**ErrorCode property**

The error code of the exception.

**Prototypes**

```
' Visual Basic
Public Readonly Property ErrorCode As Integer

// C#
public int ErrorCode {get;}
```

**QAManager interface**

The QAManager class derives from [QAManagerBase interface](#) and manages non-transactional QAnywhere messaging operations.

**Prototypes**

```
' Visual Basic
Public Interface QAManager

// C#
public interface QAManager
```

**Remarks**

For a detailed description of derived behavior, see [QAManagerBase interface](#).

The QAManager can be configured for implicit or explicit acknowledgement as defined in the [AcknowledgementMode enumeration](#). To acknowledge messages as part of a transaction, use [QATransactionalManager interface](#). Use the [QAManagerFactory class](#) to create QAManager and [QATransactionalManager interface](#) objects.

**QAManager members****Public methods**

Member name	Description
<a href="#">Acknowledge method</a>	Acknowledges that the client application successfully received a QAnywhere message.
<a href="#">AcknowledgeAll method</a>	Acknowledges that the client application successfully received QAnywhere messages. All unacknowledged messages are acknowledged.

Member name	Description
<a href="#">AcknowledgeUntil method</a>	Acknowledges the given QAMessage instance and all unacknowledged messages received before the given message.
<a href="#">Open method</a>	Open the QAManager with the given <a href="#">AcknowledgementMode enumeration</a> value.
<a href="#">Recover method</a>	Forces all unacknowledged messages into a state of unreceived.

## Acknowledge method

Acknowledges that the client application successfully received a QAnywhere message.

### Prototypes

#### ' Visual Basic

```
Public Sub Acknowledge( _  
    ByVal msg As QAMessage _  
)
```

#### // C#

```
public void Acknowledge(  
    QAMessage msg  
);
```

### Parameters

- ◆ **msg** the message to acknowledge.

### Remarks

*Note:* when a QAMessage is acknowledged, its status property changes to [StatusCodes enumeration](#).RECEIVED. When a QAMessage [STATUS field](#) message property changes to [StatusCodes enumeration](#).RECEIVED, it can be deleted using the default delete rule.

For more information about delete rules, see [“Message delete rules” on page 239](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem acknowledging the message.

### See also

- ◆ [“QAManager interface” on page 271](#)
- ◆ [“QAManager members” on page 271](#)
- ◆ [“QAManager interface” on page 271](#)
- ◆ [“AcknowledgeUntil method” on page 273](#)
- ◆ [“AcknowledgeAll method” on page 273](#)

## AcknowledgeAll method

Acknowledges that the client application successfully received QAnywhere messages. All unacknowledged messages are acknowledged.

### Prototypes

```
' Visual Basic  
Public Sub AcknowledgeAll()
```

```
// C#  
public void AcknowledgeAll();
```

### Remarks

*Note:* when a QAMessage is acknowledged, its **STATUS** field property changes to [StatusCodes enumeration.RECEIVED](#). When a QAMessage status changes to [StatusCodes enumeration.RECEIVED](#), it can be deleted using the default delete rule.

For more information about delete rules, see [“Message delete rules” on page 239](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem acknowledging the messages.

### See also

- ◆ [“QAManager interface” on page 271](#)
- ◆ [“QAManager members” on page 271](#)
- ◆ [“QAManager interface” on page 271](#)
- ◆ [“Acknowledge method” on page 272](#)
- ◆ [“AcknowledgeUntil method” on page 273](#)

## AcknowledgeUntil method

Acknowledges the given QAMessage instance and all unacknowledged messages received before the given message.

### Prototypes

```
' Visual Basic  
Public Sub AcknowledgeUntil( _  
    ByVal msg As QAMessage _  
)
```

```
// C#  
public void AcknowledgeUntil(  
    QAMessage msg  
);
```

### Parameters

- ◆ **msg** The last message to acknowledge. All earlier unacknowledged messages are also acknowledged.

## Remarks

*Note:* when a QAMessage is acknowledged, its [MessageProperties class.STATUS](#) property changes to [StatusCodes.RECEIVED](#). When a QAMessage status changes to [StatusCodes enumeration.RECEIVED](#), it can be deleted using the default delete rule.

For more information about delete rules, see [“Message delete rules” on page 239](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem acknowledging the messages.

## See also

- ◆ [“QAManager interface” on page 271](#)
- ◆ [“QAManager members” on page 271](#)
- ◆ [“QAManager interface” on page 271](#)
- ◆ [“Acknowledge method” on page 272](#)
- ◆ [“AcknowledgeAll method” on page 273](#)

## Open method

Open the QAManager with the given [AcknowledgementMode enumeration](#) value.

## Prototypes

```
' Visual Basic
Public Sub Open( _
    ByVal mode As AcknowledgementMode _
)

// C#
public void Open(
    AcknowledgementMode mode
);
```

## Parameters

- ◆ **mode** The acknowledgement mode, one of [AcknowledgementMode enumeration.EXPLICIT\\_ACKNOWLEDGEMENT](#) or [AcknowledgementMode enumeration.IMPLICIT\\_ACKNOWLEDGEMENT](#).

## Remarks

The Open method must be the first method called after creating a QAManager.

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem opening the QAManager instance.

## See also

- ◆ [“QAManager interface” on page 271](#)
- ◆ [“QAManager members” on page 271](#)
- ◆ [“QAManager interface” on page 271](#)

## Recover method

Forces all unacknowledged messages into a state of unreceived.

### Prototypes

```
' Visual Basic  
Public Sub Recover()
```

```
// C#  
public void Recover();
```

### Remarks

That is, these messages must be received again using [GetMessage method](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem recovering.

### See also

- ◆ [“QAManager interface” on page 271](#)
- ◆ [“QAManager members” on page 271](#)
- ◆ [“QAManager interface” on page 271](#)

## QAManagerBase interface

This class acts as a base class for [QATransactionalManager interface](#) and [QAManager interface](#), which manage transactional and non-transactional messaging, respectively.

### Prototypes

```
' Visual Basic  
Public Interface QAManagerBase
```

```
// C#  
public interface QAManagerBase
```

### Remarks

Use the [Start method](#) to allow a QAManagerBase instance to listen for messages. There must be only a single instance of QAManagerBase per thread in your application.

You can use instances of this class to create and manage QAnywhere messages. Use the [CreateBinaryMessage method](#) and [CreateTextMessage method](#) to create appropriate [QAMessage interface](#) instances. [QAMessage interface](#) instances provide a variety of methods to set message content and properties.

To send QAnywhere messages, use the [PutMessage method](#) to place the addressed message in the local message store queue. The message is transmitted by the QAnywhere Agent based on its transmission policies or when you call [TriggerSendReceive method](#).

For more information about qaagent transmission policies, see [“Determining when message transmission should occur on the client” on page 36](#).

Messages are released from memory when you close a QAManagerBase instance using the [Close method](#).

You can use [LastError property](#) and [LastErrorMessage property](#) to return error information when a [QAException class](#) occurs. You may also obtain the error information from the [QAException class](#) object.

QAManagerBase also provides methods to set and get message store properties.

For more information, see “[Client message store properties](#)” on [page 215](#) and the [MessageStoreProperties class](#).

## QAManagerBase members

### Public properties

Member name	Description
<a href="#">LastError property</a>	The error code associated with the last executed QAManagerBase method.
<a href="#">LastErrorMessage property</a>	The error text associated with the last executed QAManagerBase method.
<a href="#">Mode property</a>	Returns the QAManager acknowledgement mode for received messages.

### Public methods

Member name	Description
<a href="#">BrowseMessages method</a>	Browses all available messages in the message store.
<a href="#">BrowseMessages method</a>	This method is deprecated. Use the <a href="#">BrowseMessagesByQueue method</a> instead.
<a href="#">BrowseMessagesByID method</a>	Browses the message with the given message ID.
<a href="#">BrowseMessagesByQueue method</a>	Browses the next available messages waiting that have been sent to the given address.
<a href="#">BrowseMessagesBySelector method</a>	Browses messages queued in the message store that satisfy the given selector.
<a href="#">CancelMessage method</a>	Cancels the message with the given message ID.
<a href="#">Close method</a>	Closes the connection to the QAnywhere message system and releases any resources used by the <a href="#">QAManagerBase interface</a> .
<a href="#">CreateBinaryMessage method</a>	Creates a <a href="#">QABinaryMessage interface</a> object.
<a href="#">CreateTextMessage method</a>	Creates a <a href="#">QATextMessage interface</a> object.
<a href="#">GetBooleanStoreProperty method</a>	Gets a boolean value for a pre-defined or custom message store property.

Member name	Description
<a href="#">GetDoubleStoreProperty method</a>	Gets a double value for a pre-defined or custom message store property.
<a href="#">GetFloatStoreProperty method</a>	Gets a float value for a pre-defined or custom message store property.
<a href="#">GetIntStoreProperty method</a>	Gets a int value for a pre-defined or custom message store property.
<a href="#">GetLongStoreProperty method</a>	Gets a long value for a pre-defined or custom message store property.
<a href="#">GetMessage method</a>	Returns the next available <a href="#">QAMessage interface</a> sent to the specified address.
<a href="#">GetMessageBySelector method</a>	Returns the next available <a href="#">QAMessage interface</a> sent to the specified address that satisfies the given selector.
<a href="#">GetMessageBySelectorNoWait method</a>	Returns the next available <a href="#">QAMessage interface</a> sent to the given address that satisfies the given selector.
<a href="#">GetMessageBySelectorTimeout method</a>	Returns the next available <a href="#">QAMessage interface</a> sent to the given address that satisfies the given selector.
<a href="#">GetMessageNoWait method</a>	Returns the next available <a href="#">QAMessage interface</a> sent to the given address.
<a href="#">GetMessageTimeout method</a>	Returns the next available <a href="#">QAMessage interface</a> sent to the given address.
<a href="#">GetQueueDepth method</a>	Returns the depth of a queue, based on a given filter.
<a href="#">GetQueueDepth method</a>	Returns the total depth of all queues, based on a given filter.
<a href="#">GetSbyteStoreProperty method</a>	Gets a signed byte value for a pre-defined or custom message store property.
<a href="#">GetShortStoreProperty method</a>	Gets a short value for a pre-defined or custom message store property.
<a href="#">GetStoreProperty method</a>	Gets a System.Object representing a message store property.
<a href="#">GetStorePropertyNames method</a>	Gets an enumerator over the message store property names.
<a href="#">GetStringStoreProperty method</a>	Gets a string value for a pre-defined or custom message store property.
<a href="#">PutMessage method</a>	Prepares a message to send to another QAnywhere client.
<a href="#">PutMessageTimeToLive method</a>	Prepares a message to send to another QAnywhere client.
<a href="#">SetBooleanStoreProperty method</a>	Sets a pre-defined or custom message store property to a boolean value.
<a href="#">SetDoubleStoreProperty method</a>	Sets a pre-defined or custom message store property to a double value.
<a href="#">SetFloatStoreProperty method</a>	Sets a pre-defined or custom message store property to a float value.

Member name	Description
<a href="#">SetIntStoreProperty method</a>	Sets a pre-defined or custom message store property to a int value.
<a href="#">SetLongStoreProperty method</a>	Sets a pre-defined or custom message store property to a long value.
<a href="#">SetMessageListener method</a>	Sets a <a href="#">MessageListener delegate</a> delegate to receive QAnywhere messages asynchronously.
<a href="#">SetMessageListenerBySelector method</a>	Sets a <a href="#">MessageListener delegate</a> delegate to receive QAnywhere messages asynchronously, with a message selector.
<a href="#">SetProperty method</a>	Allows you to set QAnywhere Manager configuration properties programmatically.
<a href="#">SetSbyteStoreProperty method</a>	Sets a pre-defined or custom message store property to a sbyte value.
<a href="#">SetShortStoreProperty method</a>	Sets a pre-defined or custom message store property to a short value.
<a href="#">SetStoreProperty method</a>	Sets a pre-defined or custom message store property to a System.Object value.
<a href="#">SetStringStoreProperty method</a>	Sets a pre-defined or custom message store property to a string value.
<a href="#">Start method</a>	Starts the QAManagerBase for receiving incoming messages in message listeners. The QAManagerBase does not need to be started if there are no message listeners set, ie. if messages are received with the GetMessage methods. It is not recommended to use the GetMessage methods as well as message listeners for receiving messages, one should use one or the other of the asynchronous (message listener) or synchronous (GetMessage) models. Any calls to Start() beyond the first without an intervening <a href="#">Stop method</a> call are ignored.
<a href="#">Stop method</a>	Stops the QAManagerBase's reception of incoming messages.
<a href="#">TriggerSendReceive method</a>	Causes a synchronization with the QAnywhere message server, uploading any messages addressed to other clients, and downloading any messages addressed to the local client.

## LastError property

The error code associated with the last executed QAManagerBase method.

### Prototypes

**' Visual Basic**

Public Readonly Property **LastError** As Integer

**// C#**

public int **LastError** {get;}

### Return value

The error code.

## Remarks

A value of 0 indicates no error. You can retrieve this property after catching a [QAException class](#).

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“QAException class” on page 269](#)

## LastErrorMessage property

The error text associated with the last executed QAManagerBase method.

## Prototypes

```
' Visual Basic
Public Readonly Property LastErrorMessage As String
```

```
// C#
public string LastErrorMessage {get;}
```

## Remarks

This value is null if the [LastError property](#) is 0. You can retrieve this property after catching a [QAException class](#).

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“QAException class” on page 269](#)

## Mode property

Returns the QAManager acknowledgement mode for received messages.

## Prototypes

```
' Visual Basic
Public Readonly Property Mode As AcknowledgementMode
```

```
// C#
public AcknowledgementMode Mode {get;}
```

## Remarks

For a list of possible values, see [AcknowledgementMode enumeration](#). [AcknowledgementMode enumeration](#).EXPLICIT\_ACKNOWLEDGEMENT and [AcknowledgementMode enumeration](#).IMPLICIT\_ACKNOWLEDGEMENT apply to QAManager instances; [AcknowledgementMode enumeration](#).TRANSACTIONAL is the mode for QATransactionalManager instances.

## BrowseMessages method

Browses all available messages in the message store.

### Prototypes

**' Visual Basic**

Overloads Public Function **BrowseMessages()** As System.Collections.IEnumerator

**// C#**

public System.Collections.IEnumerator **BrowseMessages()**;

### Return value

An enumerator over the available messages.

### Remarks

The messages are just being browsed, so they cannot be acknowledged. Because browsing messages allocates native resources, you should call the `Reset()` method of the enumerator when you are done with it. If it is not called, the native resources will not be freed until this `QAManagerBase` object is freed.

Use [GetMessage method](#) to receive messages so they can be acknowledged.

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“BrowseMessagesByQueue method” on page 282](#)
- ◆ [“BrowseMessagesByID method” on page 281](#)
- ◆ [“BrowseMessages method” on page 280](#)

## BrowseMessages method

This method is deprecated. Use the [BrowseMessagesByQueue method](#) instead.

### Prototypes

**' Visual Basic**

Overloads Public Function **BrowseMessages(** \_  
    ByVal *address* As String \_  
    **)** As System.Collections.IEnumerator

**// C#**

public System.Collections.IEnumerator **BrowseMessages(**  
    string *address*  
    **);**

### Parameters

- ◆ **address** The address of the messages.

### Return value

An enumerator over the available messages.

## Remarks

Browses the next available messages waiting that have been sent to a given address. The address parameter takes the form 'store-id\queue-name' or 'queue-name'. The messages are just being browsed, so they cannot be acknowledged.

Because browsing messages allocates native resources, you should call the `Reset()` method of the enumerator when you are done with it. If it is not called, the native resources will not be freed until this [QAManagerBase interface](#) object is freed.

Use [GetMessage method](#) to receive messages so they can be acknowledged.

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“BrowseMessagesByQueue method” on page 282](#)
- ◆ [“BrowseMessagesByID method” on page 281](#)
- ◆ [“BrowseMessagesBySelector method” on page 282](#)
- ◆ [“BrowseMessages method” on page 280](#)

## BrowseMessagesByID method

Browses the message with the given message ID.

## Prototypes

### ' Visual Basic

```
Public Function BrowseMessagesByID( _  
    ByVal msgid As String _  
) As System.Collections.IEnumerator
```

### // C#

```
public System.Collections.IEnumerator BrowseMessagesByID(  
    string msgid  
);
```

## Parameters

- ◆ **msgid** The message id of the message.

## Return value

An enumerator containing 0 or 1 messages.

## Remarks

The message is just being browsed, so it cannot be acknowledged. Because browsing messages allocates native resources, you should call the `Reset()` method of the enumerator when you are done with it. If it is not called, the native resources will not be freed until this `QAManagerBase` object is freed.

Use [GetMessage method](#) to receive messages so they can be acknowledged.

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“BrowseMessagesByQueue method” on page 282](#)
- ◆ [“BrowseMessages method” on page 280](#)
- ◆ [“BrowseMessages method” on page 280](#)

## BrowseMessagesByQueue method

Browses the next available messages waiting that have been sent to the given address.

### Prototypes

#### ' Visual Basic

```
Public Function BrowseMessagesByQueue( _  
    ByVal address As String _  
) As System.Collections.IEnumerator
```

#### // C#

```
public System.Collections.IEnumerator BrowseMessagesByQueue(  
    string address  
);
```

### Parameters

- ◆ **address** The address of the messages.

### Return value

An enumerator over the available messages.

### Remarks

The messages are just being browsed, so they cannot be acknowledged. Because browsing messages allocates native resources, you should call the `Reset()` method of the enumerator when you are done with it. If it is not called, the native resources will not be freed until this `QAManagerBase` object is freed.

Use [GetMessage method](#) to receive messages so they can be acknowledged.

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“BrowseMessagesByID method” on page 281](#)
- ◆ [“BrowseMessages method” on page 280](#)
- ◆ [“BrowseMessages method” on page 280](#)

## BrowseMessagesBySelector method

Browses messages queued in the message store that satisfy the given selector.

## Prototypes

```
' Visual Basic
Public Function BrowseMessagesBySelector( _
    ByVal selector As String _
) As System.Collections.IEnumerator

// C#
public System.Collections.IEnumerator BrowseMessagesBySelector(
    string selector
);
```

## Parameters

◆ **selector** The selector.

## Return value

An enumerator over the available messages.

## Remarks

The message is just being browsed, so it cannot be acknowledged. Because browsing messages allocates native resources, you should call the `Reset()` method of the enumerator when you are done with it. If it is not called, the native resources will not be freed until this `QAManagerBase` object is freed.

Use [GetMessage method](#) to receive messages so they can be acknowledged.

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“BrowseMessagesByQueue method” on page 282](#)
- ◆ [“BrowseMessages method” on page 280](#)
- ◆ [“BrowseMessages method” on page 280](#)
- ◆ [“BrowseMessagesByID method” on page 281](#)

## CancelMessage method

Cancels the message with the given message ID.

## Prototypes

```
' Visual Basic
Public Sub CancelMessage( _
    ByVal msgid As String _
)

// C#
public void CancelMessage(
    string msgid
);
```

## Parameters

◆ **msgid** The message ID of the message to cancel.

## Remarks

CancelMessage puts a message into a cancelled state before it is transmitted. With the default delete rules of the QAnywhere Agent, cancelled messages will eventually be deleted from the message store.

CancelMessage will fail if the message is already in a final state, or if it has been transmitted to the central messaging server.

For more information about delete rules, see [“Message delete rules” on page 239](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem cancelling the message.

## Close method

Closes the connection to the QAnywhere message system and releases any resources used by the [QAManagerBase interface](#).

## Prototypes

```
' Visual Basic  
Public Sub Close()
```

```
// C#  
public void Close();
```

## Remarks

Additional calls to Close() following the first are ignored. Any subsequent calls to a QAManagerBase method, other than Close(), will result in a [QAException class](#). You must create and open a new [QAManagerBase interface](#) instance in this case.

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem closing the QAManagerBase instance.

## CreateBinaryMessage method

Creates a [QABinaryMessage interface](#) object.

## Prototypes

```
' Visual Basic  
Public Function CreateBinaryMessage() As QABinaryMessage
```

```
// C#  
public QABinaryMessage CreateBinaryMessage();
```

## Return value

A new [QABinaryMessage interface](#) instance.

## Remarks

A [QABinaryMessage](#) object is used to send a message containing a message body of uninterpreted bytes.

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem creating the message.

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“QABinaryMessage interface” on page 255](#)

## CreateTextMessage method

Creates a [QATextMessage interface](#) object.

## Prototypes

' **Visual Basic**  
Public Function **CreateTextMessage()** As [QATextMessage](#)

// **C#**  
public [QATextMessage](#) **CreateTextMessage();**

## Return value

A new [QATextMessage interface](#) instance.

## Remarks

A [QATextMessage interface](#) object is used to send a message containing a string message body.

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem creating the message.

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“QATextMessage interface” on page 335](#)

## GetBooleanStoreProperty method

Gets a boolean value for a pre-defined or custom message store property.

## Prototypes

' **Visual Basic**  
Public Function **GetBooleanStoreProperty**( \_  
    ByVal *propName* As String \_  
    ) As Boolean

```
// C#  
public bool GetBooleanStoreProperty(  
    string propName  
);
```

#### Parameters

- ◆ **propName** The pre-defined or custom property name.

#### Return value

The boolean property value.

#### Remarks

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#). For more information, see “[Client message store properties](#)” on page 215.

#### Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

#### See also

- ◆ “[QAManagerBase interface](#)” on page 275
- ◆ “[QAManagerBase members](#)” on page 276
- ◆ “[MessageStoreProperties class](#)” on page 253

### **GetDoubleStoreProperty method**

Gets a double value for a pre-defined or custom message store property.

#### Prototypes

```
' Visual Basic  
Public Function GetDoubleStoreProperty( _  
    ByVal propName As String _  
) As Double
```

```
// C#  
public double GetDoubleStoreProperty(  
    string propName  
);
```

#### Parameters

- ◆ **propName** The pre-defined or custom property name.

#### Return value

The double property value.

## Remarks

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

## GetFloatStoreProperty method

Gets a float value for a pre-defined or custom message store property.

## Prototypes

```
' Visual Basic
Public Function GetFloatStoreProperty( _
    ByVal propName As String _
) As Single
```

```
// C#
public float GetFloatStoreProperty(
    string propName
);
```

## Parameters

- ◆ **propName** The pre-defined or custom property name.

## Return value

The float property value.

## Remarks

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

### GetIntStoreProperty method

Gets a int value for a pre-defined or custom message store property.

#### Prototypes

```
' Visual Basic
Public Function GetIntStoreProperty( _
    ByVal propName As String _
) As Integer
```

```
// C#
public int GetIntStoreProperty(
    string propName
);
```

#### Parameters

- ◆ **propName** The pre-defined or custom property name.

#### Return value

The integer property value.

#### Remarks

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

#### Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

### GetLongStoreProperty method

Gets a long value for a pre-defined or custom message store property.

## Prototypes

```
' Visual Basic
Public Function GetLongStoreProperty( _
    ByVal propName As String _
) As Long

// C#
public long GetLongStoreProperty(
    string propName
);
```

## Parameters

- ◆ **propName** The pre-defined or custom property name.

## Return value

The long property value.

## Remarks

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#)

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

## GetMessage method

Returns the next available [QAMessage interface](#) sent to the specified address.

## Prototypes

```
' Visual Basic
Public Function GetMessage( _
    ByVal address As String _
) As QAMessage

// C#
public QAMessage GetMessage(
    string address
);
```

**Parameters**

- ◆ **address** Specifies the queue name used by the QAnywhere client to receive messages.

**Return value**

The next [QAMessage interface](#), or null if no message is available.

**Remarks**

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'.

If there is no message available, this call blocks indefinitely until a message is available. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

**Exceptions**

- ◆ [QAException class](#) - Thrown if there is a problem getting the message.

**GetMessageBySelector method**

Returns the next available [QAMessage interface](#) sent to the specified address that satisfies the given selector.

**Prototypes**

```
' Visual Basic
Public Function GetMessageBySelector( _
    ByVal address As String, _
    ByVal selector As String _
) As QAMessage

// C#
public QAMessage GetMessageBySelector(
    string address,
    string selector
);
```

**Parameters**

- ◆ **address** This address specifies the queue name used by the QAnywhere client to receive messages.
- ◆ **selector** The selector.

**Return value**

The next [QAMessage interface](#), or null if no message is available.

**Remarks**

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'.

If there is no message available, this call blocks indefinitely until a message is available. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem getting the message.

### GetMessageBySelectorNoWait method

Returns the next available [QAMessage interface](#) sent to the given address that satisfies the given selector.

### Prototypes

```
' Visual Basic
Public Function GetMessageBySelectorNoWait( _
    ByVal address As String, _
    ByVal selector As String _
) As QAMessage

// C#
public QAMessage GetMessageBySelectorNoWait(
    string address,
    string selector
);
```

### Parameters

- ◆ **address** Specifies the queue name used by the QAnywhere client to receive messages.
- ◆ **selector** The selector.

### Return value

The next available message or null there are no available message.

### Remarks

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method returns immediately. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem getting the message.

### GetMessageBySelectorTimeout method

Returns the next available [QAMessage interface](#) sent to the given address that satisfies the given selector.

## Prototypes

### ' Visual Basic

```
Public Function GetMessageBySelectorTimeout( _  
    ByVal address As String, _  
    ByVal selector As String, _  
    ByVal timeout As Long _  
    ) As QAMessage
```

### // C#

```
public QAMessage GetMessageBySelectorTimeout(  
    string address,  
    string selector,  
    long timeout  
    );
```

## Parameters

- ◆ **address** Specifies the queue name used by the QAnywhere client to receive messages.
- ◆ **selector** The selector.
- ◆ **timeout** The time to wait, in milliseconds, for a message to become available.

## Return value

The next [QAMessage interface](#), or null if no message is available.

## Remarks

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method waits for the specified timeout and then returns. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem getting the message.

## GetMessageNoWait method

Returns the next available [QAMessage interface](#) sent to the given address.

## Prototypes

### ' Visual Basic

```
Public Function GetMessageNoWait( _  
    ByVal address As String _  
    ) As QAMessage
```

### // C#

```
public QAMessage GetMessageNoWait(  
    string address  
    );
```

## Parameters

- ◆ **address** this address specifies the queue name used by the QAnywhere client to receive messages.

## Return value

The next available message or null there is no available message.

## Remarks

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method returns immediately. Use this method to receive messages synchronously. For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem getting the message.

## GetMessageTimeout method

Returns the next available [QAMessage interface](#) sent to the given address.

## Prototypes

### ' Visual Basic

```
Public Function GetMessageTimeout( _  
    ByVal address As String, _  
    ByVal timeout As Long _  
) As QAMessage
```

### // C#

```
public QAMessage GetMessageTimeout(  
    string address,  
    long timeout  
);
```

## Parameters

- ◆ **address** Specifies the queue name used by the QAnywhere client to receive messages.
- ◆ **timeout** The time to wait, in milliseconds, for a message to become available.

## Return value

The next [QAMessage interface](#), or null if no message is available.

## Remarks

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'.

If no message is available, this method waits for the specified timeout and then returns. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem getting the message.

## GetQueueDepth method

Returns the depth of a queue, based on a given filter.

### Prototypes

```
' Visual Basic
Overloads Public Function GetQueueDepth( _
    ByVal address As String, _
    ByVal filter As QueueDepthFilter _
) As Integer
```

```
// C#
public int GetQueueDepth(
    string address,
    QueueDepthFilter filter
);
```

### Parameters

- ◆ **filter** A filter indicating incoming messages, outgoing messages, or all messages.
- ◆ **address** The queue name.

### Return value

The number of messages.

### Remarks

The depth of the queue is the number of messages which have not been received (for example, using [GetMessage method](#)).

### Exceptions

- ◆ [QAException class](#) - Thrown if there was an error.

## GetQueueDepth method

Returns the total depth of all queues, based on a given filter.

### Prototypes

```
' Visual Basic
Overloads Public Function GetQueueDepth( _
    ByVal filter As QueueDepthFilter _
) As Integer
```

```
// C#
public int GetQueueDepth(
);
```

```
QueueDepthFilter filter
);
```

### Parameters

- ◆ **filter** A filter indicating incoming messages, outgoing messages, or all messages.

### Return value

The number of messages.

### Remarks

The depth of the queue is the number of messages which have not been received (for example, using [GetMessage method](#)).

### Exceptions

- ◆ [QAException class](#) - Thrown if there was an error.

## GetSbyteStoreProperty method

Gets a signed byte value for a pre-defined or custom message store property.

### Prototypes

```
' Visual Basic
Public Function GetSbyteStoreProperty( _
    ByVal propName As String _
) As System.SByte

// C#
public System.Sbyte GetSbyteStoreProperty(
    string propName
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.

### Return value

The signed byte property value.

### Remarks

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

### GetShortStoreProperty method

Gets a short value for a pre-defined or custom message store property.

#### Prototypes

##### ' Visual Basic

```
Public Function GetShortStoreProperty( _  
    ByVal propName As String _  
) As Short
```

##### // C#

```
public short GetShortStoreProperty(  
    string propName  
);
```

#### Parameters

- ◆ **propName** the pre-defined or custom property name.

#### Return value

The short property value.

#### Remarks

You can use this method to access pre-defined or user-defined client store properties. For a list of pre-defined properties, see [MessageStoreProperties class](#). For more information, see [“Client message store properties” on page 215](#).

#### Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

### GetStoreProperty method

Gets a System.Object representing a message store property.

## Prototypes

```
' Visual Basic
Public Function GetStoreProperty( _
    ByVal propName As String _
) As Object

// C#
public object GetStoreProperty(
    string propName
);
```

## Parameters

- ◆ **propName** The pre-defined or custom property name.

## Return value

The property value.

## Remarks

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if the property does not exist

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

## GetStorePropertyNames method

Gets an enumerator over the message store property names.

## Prototypes

```
' Visual Basic
Public Function GetStorePropertyNames() As System.Collections.IEnumerator

// C#
public System.Collections.IEnumerator GetStorePropertyNames();
```

## Return value

An enumerator over the message store property names.

## Remarks

For more information about client store properties, see [“Client message store properties” on page 215](#).

## GetStringStoreProperty method

Gets a string value for a pre-defined or custom message store property.

### Prototypes

```
' Visual Basic
Public Function GetStringStoreProperty( _
    ByVal propName As String _
) As String

// C#
public string GetStringStoreProperty(
    string propName
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.

### Return value

The string property value or null if the property does not exist.

### Remarks

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

## PutMessage method

Prepares a message to send to another QAnywhere client.

### Prototypes

```
' Visual Basic
Public Sub PutMessage( _
    ByVal address As String, _
    ByVal msg As QAMessage _
)

// C#
public void PutMessage(
    string address,
    QAMessage msg
);
```

## Parameters

- ◆ **address** The address of the message specifying the destination queue name.
- ◆ **msg** The message to put in the local message store for transmission.

## Remarks

The PutMessage method inserts a message and a destination address into your local message store. The time of message transmission depends on QAnywhere Agent transmission policies.

For more information, see [“Determining when message transmission should occur on the client” on page 36.](#)

The address takes the form 'id\queue-name', where 'id' is the destination message store ID and 'queue-name' identifies a queue that is used by the destination QAnywhere client to listen for or receive messages.

For more information about QAnywhere addresses, see [“QAnywhere message addresses” on page 50.](#)

## Exceptions

- ◆ [QAEException class](#) - Thrown if there is a problem putting the message.

## See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“PutMessageTimeToLive method” on page 299](#)

## PutMessageTimeToLive method

Prepares a message to send to another QAnywhere client.

## Prototypes

### ' Visual Basic

```
Public Sub PutMessageTimeToLive( _  
    ByVal address As String, _  
    ByVal msg As QAMessage, _  
    ByVal ttl As Long _  
)
```

### // C#

```
public void PutMessageTimeToLive(  
    string address,  
    QAMessage msg,  
    long ttl  
);
```

## Parameters

- ◆ **address** The address of the message specifying the destination queue name.
- ◆ **msg** The message to put.

- ◆ **ttl** The delay, in milliseconds, before the message will expire if it has not been delivered. A value of 0 indicates the message will not expire.

### Remarks

The PutMessageTimeToLive method inserts a message and a destination address into your local message store. The time of message transmission depends on QAnywhere Agent transmission policies. However, if the next message transmission time exceeds the given time-to-live value, the message expires.

For more information, see [“Determining when message transmission should occur on the client” on page 36.](#)

The address takes the form 'id\queue-name', where 'id' is the destination message store id and 'queue-name' identifies a queue that is used by the destination QAnywhere client to listen for or receive messages.

For more information about QAnywhere addresses, see [“QAnywhere message addresses” on page 50.](#)

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem putting the message.

## SetBooleanStoreProperty method

Sets a pre-defined or custom message store property to a boolean value.

### Prototypes

```
' Visual Basic
Public Sub SetBooleanStoreProperty( _
    ByVal propName As String, _
    ByVal val As Boolean _
)

// C#
public void SetBooleanStoreProperty(
    string propName,
    bool val
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The boolean property value.

### Remarks

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215.](#)

### See also

- ◆ [“QAManagerBase interface” on page 275](#)

- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

## SetDoubleStoreProperty method

Sets a pre-defined or custom message store property to a double value.

### Prototypes

```
' Visual Basic
Public Sub SetDoubleStoreProperty( _
    ByVal propName As String, _
    ByVal val As Double _
)

// C#
public void SetDoubleStoreProperty(
    string propName,
    double val
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The double property value.

### Remarks

You can use this method to set pre-defined or user-defined client. store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

## SetFloatStoreProperty method

Sets a pre-defined or custom message store property to a float value.

### Prototypes

```
' Visual Basic
Public Sub SetFloatStoreProperty( _
    ByVal propName As String, _
    ByVal val As Single _
)
```

```
// C#  
public void SetFloatStoreProperty(  
    string propName,  
    float val  
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The float property value.

### Remarks

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

## SetIntStoreProperty method

Sets a pre-defined or custom message store property to a int value.

### Prototypes

```
' Visual Basic  
Public Sub SetIntStoreProperty( _  
    ByVal propName As String, _  
    ByVal val As Integer _  
)
```

```
// C#  
public void SetIntStoreProperty(  
    string propName,  
    int val  
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The int property value.

### Remarks

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

**See also**

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

**SetLongStoreProperty method**

Sets a pre-defined or custom message store property to a long value.

**Prototypes**

```
' Visual Basic
Public Sub SetLongStoreProperty( _
    ByVal propName As String, _
    ByVal val As Long _
)

// C#
public void SetLongStoreProperty(
    string propName,
    long val
);
```

**Parameters**

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The long property value

**Remarks**

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

**See also**

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

**SetMessageListener method**

Sets a [MessageListener delegate](#) delegate to receive QAnywhere messages asynchronously.

**Prototypes**

```
' Visual Basic
Public Sub SetMessageListener( _
    ByVal address As String, _
    ByVal listener As MessageListener _
)
```

```
// C#  
public void SetMessageListener(  
    string address,  
    MessageListener listener  
);
```

### Parameters

- ◆ **address** The address of messages.
- ◆ **listener** The listener to register.

### Remarks

Use this method to receive message asynchronously.

MessageListener delegate accepts a single QAMessage parameter.

The SetMessageListener address parameter specifies a local queue name used to receive the message. You can only have one listener delegate assigned to a given queue.

If you want to listen for QAnywhere system messages, including push notifications and network status changes, specify "system" as the queue name.

For more information, see [“Receiving messages asynchronously” on page 76](#).

## SetMessageListenerBySelector method

Sets a [MessageListener delegate](#) delegate to receive QAnywhere messages asynchronously, with a message selector.

### Prototypes

```
' Visual Basic  
Public Sub SetMessageListenerBySelector( _  
    ByVal address As String, _  
    ByVal selector As String, _  
    ByVal listener As MessageListener _  
)
```

```
// C#  
public void SetMessageListenerBySelector(  
    string address,  
    string selector,  
    MessageListener listener  
);
```

### Parameters

- ◆ **address** The address of messages.
- ◆ **listener** The listener to register.
- ◆ **selector** The selector to be used to filter the messages to be received.

## Remarks

Use this method to receive message asynchronously.

MessageListener delegate accepts a single QAMessage parameter.

The SetMessageListener address parameter specifies a local queue name used to receive the message. You can only have one listener delegate assigned to a given queue. The selector parameter specifies a selector to be used to filter the messages to be received on the given address.

If you want to listen for QAnywhere system messages, including push notifications and network status changes, specify "system" as the queue name.

For more information, see [“Receiving messages asynchronously” on page 76](#) and [“System queue” on page 50](#).

## SetProperty method

Allows you to set QAnywhere Manager configuration properties programmatically.

## Prototypes

```
' Visual Basic
Public Sub SetProperty( _
    ByVal name As String, _
    ByVal val As String _
)
```

```
// C#
public void SetProperty(
    string name,
    string val
);
```

## Parameters

- ◆ **name** The QAnywhere Manager configuration property name.
- ◆ **val** The QAnywhere Manager configuration property value

## Remarks

You can use this method to override default QAnywhere Manager configuration properties by specifying a property name and value. For a list of properties, see [“QAnywhere manager configuration properties” on page 62](#).

You can also set QAnywhere Manager configuration properties using a properties file and the [CreateQAManager method](#).

For more information, see [“Setting QAnywhere manager configuration properties in a file” on page 62](#).

*Note:* you must set required properties before calling [Open method](#) or [Open method](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem setting the property.

## SetSbyteStoreProperty method

Sets a pre-defined or custom message store property to a sbyte value.

### Prototypes

```
' Visual Basic
Public Sub SetSbyteStoreProperty( _
    ByVal propName As String, _
    ByVal val As System.SByte _
)

// C#
public void SetSbyteStoreProperty(
    string propName,
    System.Sbyte val
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The sbyte property value.

### Remarks

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

### See also

- ◆ “[QAManagerBase interface](#)” on page 275
- ◆ “[QAManagerBase members](#)” on page 276
- ◆ “[MessageStoreProperties class](#)” on page 253

## SetShortStoreProperty method

Sets a pre-defined or custom message store property to a short value.

### Prototypes

```
' Visual Basic
Public Sub SetShortStoreProperty( _
    ByVal propName As String, _
    ByVal val As Short _
)

// C#
public void SetShortStoreProperty(
    string propName,
    short val
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The short property value.

### Remarks

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#). For more information, see “[Client message store properties](#)” on page 215.

### See also

- ◆ “[QAManagerBase interface](#)” on page 275
- ◆ “[QAManagerBase members](#)” on page 276
- ◆ “[MessageStoreProperties class](#)” on page 253

## SetStoreProperty method

Sets a pre-defined or custom message store property to a System.Object value.

### Prototypes

```
' Visual Basic
Public Sub SetStoreProperty( _
    ByVal propName As String, _
    ByVal val As Object _
)

// C#
public void SetStoreProperty(
    string propName,
    object val
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The property value.

### Remarks

The property type must be one of the acceptable primitive types, or String. You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

### See also

- ◆ “[QAManagerBase interface](#)” on page 275
- ◆ “[QAManagerBase members](#)” on page 276

- ◆ [“MessageStoreProperties class” on page 253](#)

## SetStringStoreProperty method

Sets a pre-defined or custom message store property to a string value.

### Prototypes

```
' Visual Basic
Public Sub SetStringStoreProperty( _
    ByVal propName As String, _
    ByVal val As String _
)

// C#
public void SetStringStoreProperty(
    string propName,
    string val
);
```

### Parameters

- ◆ **propName** The pre-defined or custom property name.
- ◆ **val** The string property value.

### Remarks

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“MessageStoreProperties class” on page 253](#)

## Start method

Starts the QAManagerBase for receiving incoming messages in message listeners. The QAManagerBase does not need to be started if there are no message listeners set, ie. if messages are received with the GetMessage methods. It is not recommended to use the GetMessage methods as well as message listeners for receiving messages, one should use one or the other of the asynchronous (message listener) or synchronous (GetMessage) models. Any calls to Start() beyond the first without an intervening [Stop method](#) call are ignored.

### Prototypes

```
' Visual Basic
Public Sub Start()
```

```
// C#  
public void Start();
```

### Exceptions

- ◆ [QAEException class](#) - Thrown if there is a problem starting the QAManagerBase instance.

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“Stop method” on page 309](#)

### Stop method

Stops the QAManagerBase's reception of incoming messages.

### Prototypes

```
' Visual Basic  
Public Sub Stop()
```

```
// C#  
public void Stop();
```

### Remarks

The messages are not lost. They just won't be received until the manager is started again. Any calls to Stop () beyond the first without an intervening [Start method](#) are ignored.

### Exceptions

- ◆ [QAEException class](#) - Thrown if there is a problem stopping the QAManagerBase instance.

### See also

- ◆ [“QAManagerBase interface” on page 275](#)
- ◆ [“QAManagerBase members” on page 276](#)
- ◆ [“Start method” on page 308](#)

### TriggerSendReceive method

Causes a synchronization with the QAnywhere message server, uploading any messages addressed to other clients, and downloading any messages addressed to the local client.

### Prototypes

```
' Visual Basic  
Public Sub TriggerSendReceive()
```

```
// C#  
public void TriggerSendReceive();
```

## Remarks

QAManagerBase TriggerSendReceive results in immediate message synchronization between a QAnywhere Agent and the central messaging server. A manual TriggerSendReceive call results in immediate message transmission, independent of the QAnywhere Agent transmission policies.

QAnywhere Agent transmission policies determine how message transmission occurs. For example, message transmission can occur automatically at regular intervals, when your client receives a push notification, or when you call the [PutMessage method](#) to send a message.

For more information, see “[Determining when message transmission should occur on the client](#)” on page 36.

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem triggering the send/receive.

## See also

- ◆ “[QAManagerBase interface](#)” on page 275
- ◆ “[QAManagerBase members](#)” on page 276
- ◆ “[PutMessage method](#)” on page 298

## QAManagerFactory class

This class acts as a factory class for creating QATransactionalManager and QAManager objects.

## Prototypes

```
' Visual Basic
MustInherit Public Class QAManagerFactory
    Inherits Component
```

```
// C#
public abstract class QAManagerFactory :
    Component
```

## Remarks

You can only have one instance of QAManagerFactory.

## QAManagerFactory members

### Public static properties (shared)

Member name	Description
<a href="#">Instance property</a>	A singleton QAManagerFactory instance.
<a href="#">InstanceCount property</a>	Indicates the number of factory instances.

**Public fields**

Member name	Description
<a href="#">InstanceID field</a>	Factory ID.

**Public properties**

Member name	Description
<a href="#">LastError property</a>	The error code associated with the last executed QAManagerFactory method.
<a href="#">LastErrorMessage property</a>	The error text associated with the last executed QAManagerFactory method.

**Public methods**

Member name	Description
<a href="#">CreateQAManager method</a>	Returns a new QAManager instance with the specified properties.
<a href="#">CreateQATransactionalManager method</a>	Returns a new QATransactionalManager instance with the specified properties.

**InstanceID field**

Factory ID.

**Prototypes**

```
' Visual Basic
Public InstanceID As Integer
```

```
// C#
public int InstanceID;
```

**Instance property**

A singleton QAManagerFactory instance.

**Prototypes**

```
' Visual Basic
Public Shared ReadOnly Property Instance As QAManagerFactory
```

```
// C#
public const QAManagerFactory Instance {get;}
```

**Exceptions**

- ◆ [QAException class](#) - Thrown if there is a problem creating the manager factory.

## InstanceCount property

Indicates the number of factory instances.

### Prototypes

```
' Visual Basic  
Public Shared Readonly Property InstanceCount As Long
```

```
// C#  
public const long InstanceCount {get;}
```

## LastError property

The error code associated with the last executed QAManagerFactory method.

### Prototypes

```
' Visual Basic  
Public Readonly Property LastError As Integer
```

```
// C#  
public int LastError {get;}
```

### Return value

The error code.

### Remarks

A value of 0 indicates no error. You can retrieve this property after catching a [QAException class](#).

### See also

- ◆ [“QAManagerFactory class” on page 310](#)
- ◆ [“QAManagerFactory members” on page 310](#)
- ◆ [“QAException class” on page 269](#)

## LastErrorMessage property

The error text associated with the last executed QAManagerFactory method.

### Prototypes

```
' Visual Basic  
Public Readonly Property LastErrorMessage As String
```

```
// C#  
public string LastErrorMessage {get;}
```

### Return value

The error message.

## Remarks

This value is null if the [LastError](#) property is 0. You can retrieve this property after catching a [QAException](#) class.

## See also

- ◆ [“QAManagerFactory class” on page 310](#)
- ◆ [“QAManagerFactory members” on page 310](#)
- ◆ [“QAException class” on page 269](#)

## CreateQAManager method

Returns a new QAManager instance with the specified properties.

## Prototypes

### ' Visual Basic

```
Public Function CreateQAManager( _  
    ByVal iniFile As String _  
) As QAManager
```

### // C#

```
public QAManager CreateQAManager(  
    string iniFile  
);
```

## Parameters

- ◆ **iniFile** A properties file for configuring the QAManager instance.

## Return value

A new QAManager instance.

## Remarks

If the properties file parameter is null, the QAManager is created using default properties. You can use the  [SetProperty method](#) to set QAnywhere manager configuration properties programmatically after you create the instance.

For a list of QAnywhere manager configuration properties, see [“QAnywhere manager configuration properties” on page 62](#).

For more information, see [“Setting QAnywhere manager configuration properties in a file” on page 62](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem creating the manager.

## See also

- ◆ [“QAManagerFactory class” on page 310](#)
- ◆ [“QAManagerFactory members” on page 310](#)
- ◆ [“QAManager interface” on page 271](#)

## CreateQATransactionalManager method

Returns a new QATransactionalManager instance with the specified properties.

### Prototypes

```
' Visual Basic
Public Function CreateQATransactionalManager( _
    ByVal iniFile As String _
) As QATransactionalManager

// C#
public QATransactionalManager CreateQATransactionalManager(
    string iniFile
);
```

### Parameters

- ◆ **iniFile** A properties file for configuring the QATransactionalManager instance, or null to create the QATransactionalManager instance with default properties.

### Return value

The configured QATransactionalManager.

### Remarks

If the properties file parameter is null, the QATransactionalManager is created using default properties. You can use the [SetProperty method](#) to set QAnywhere Manager configuration properties programmatically after you create the instance.

For a list of QAnywhere Manager configuration properties, see [“QAnywhere manager configuration properties” on page 62](#).

For more information, see [“Setting QAnywhere manager configuration properties in a file” on page 62](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem creating the manager.

### See also

- ◆ [“QAManagerFactory class” on page 310](#)
- ◆ [“QAManagerFactory members” on page 310](#)
- ◆ [“QATransactionalManager interface” on page 337](#)

## QAMessage interface

Provides an interface to set message properties and header fields.

### Prototypes

```
' Visual Basic
Public Interface QAMessage
```

```
// C#
public interface QAMessage
```

### Remarks

The derived classes [QABinaryMessage interface](#) and [QATextMessage interface](#) provide specialized methods to read and write to the message body. You can use QAMessage methods to set predefined or custom message properties.

For a list of pre-defined property names, see the [MessageProperties class](#).

For more information about setting message properties and header fields, see “[Message headers and message properties](#)” on page 206.

### QAMessage members

#### Public properties

Member name	Description
<a href="#">Address property</a>	The destination address for the QAMessage instance.
<a href="#">Expiration property</a>	Gets the message's expiration value.
<a href="#">InReplyToID property</a>	The message id of the message for which this message is a reply.
<a href="#">MessageID property</a>	The globally unique message id of the message.
<a href="#">Priority property</a>	The priority of the message (ranging from 0 to 9).
<a href="#">Redelivered property</a>	Indicates whether the message has been previously received but not acknowledged.
<a href="#">ReplyToAddress property</a>	The reply to address of this message.
<a href="#">Timestamp property</a>	The message timestamp.

#### Public methods

Member name	Description
<a href="#">ClearBody method</a>	Clears the body of the message.
<a href="#">ClearProperties method</a>	Clears all the properties of the message.
<a href="#">GetBooleanProperty method</a>	Gets a boolean message property.
<a href="#">GetByteProperty method</a>	Gets a byte message property.
<a href="#">GetDoubleProperty method</a>	Gets a double message property.
<a href="#">GetFloatProperty method</a>	Gets a float message property.

Member name	Description
<a href="#">GetIntProperty method</a>	Gets an int message property.
<a href="#">GetLongProperty method</a>	Gets a long message property.
<a href="#">GetProperty method</a>	Gets a message property.
<a href="#">GetPropertyNames method</a>	Gets an enumerator over the property names of the message.
<a href="#">GetPropertyType method</a>	Returns the property type of the given property.
<a href="#">GetSbyteProperty method</a>	Gets a signed byte message property.
<a href="#">GetShortProperty method</a>	Gets a short message property.
<a href="#">GetStringProperty method</a>	Gets a string message property.
<a href="#">PropertyExists method</a>	Indicates whether the given property has been set for this message.
<a href="#">SetBooleanProperty method</a>	Sets a boolean property.
<a href="#">SetByteProperty method</a>	Sets a byte property.
<a href="#">SetDoubleProperty method</a>	Sets a double property.
<a href="#">SetFloatProperty method</a>	Sets a float property.
<a href="#">SetIntProperty method</a>	Sets an int property.
<a href="#">SetLongProperty method</a>	Sets a long property.
<a href="#">SetProperty method</a>	Sets a property.
<a href="#">SetSbyteProperty method</a>	Sets a signed byte property.
<a href="#">SetShortProperty method</a>	Sets a short property.
<a href="#">SetStringProperty method</a>	Sets a string property.

## Address property

The destination address for the QAMessage instance.

### Prototypes

#### ' Visual Basic

Public Property **Address** As String

#### // C#

```
public string Address {get;set;}
```

**Remarks**

When a message is sent, this field is ignored. After completion of a send operation, the field holds the destination address specified in [PutMessage method](#).

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**Expiration property**

Gets the message's expiration value.

**Prototypes**

```
' Visual Basic  
Public Readonly Property Expiration As Date
```

```
// C#  
public DateTime Expiration {get;}
```

**Remarks**

When a message is sent, the Expiration header field is left unassigned. After completion of the send method, it holds the expiration time of the message.

This is a read-only property because the expiration time of a message is set by adding the time-to-live argument of `QAManagerBase::PutMessageTimeToLive` to the current time.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**InReplyToID property**

The message id of the message for which this message is a reply.

**Prototypes**

```
' Visual Basic  
Public Property InReplyToID As String
```

```
// C#  
public string InReplyToID {get;set;}
```

**Remarks**

May be null.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## MessageID property

The globally unique message id of the message.

### Prototypes

```
' Visual Basic  
Public Readonly Property MessageID As String
```

```
// C#  
public string MessageID {get;}
```

### Remarks

This property is null until a message is put.

When a message is sent using [PutMessage method](#), the MessageID is null and can be ignored. When the send method returns, it contains an assigned value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## Priority property

The priority of the message (ranging from 0 to 9).

### Prototypes

```
' Visual Basic  
Public Property Priority As Integer
```

```
// C#  
public int Priority {get;set;}
```

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## Redelivered property

Indicates whether the message has been previously received but not acknowledged.

### Prototypes

```
' Visual Basic  
Public Readonly Property Redelivered As Boolean
```

```
// C#  
public bool Redelivered {get;}
```

**Remarks**

Redelivered is set by a receiving QAManager when it detects that a message being received was received before.

For example, an application receives a message using a [QAManager interface](#) opened with [AcknowledgementMode enumeration.EXPLICIT\\_ACKNOWLEDGEMENT](#), and shuts down without acknowledging the message. When the application starts again and receives the same message the Redelivered header will be true.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**ReplyToAddress property**

The reply to address of this message.

**Prototypes**

```
' Visual Basic  
Public Property ReplyToAddress As String
```

```
// C#  
public string ReplyToAddress {get;set;}
```

**Remarks**

May be null.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**Timestamp property**

The message timestamp.

**Prototypes**

```
' Visual Basic  
Public Readonly Property Timestamp As Date
```

```
// C#  
public DateTime Timestamp {get;}
```

**Remarks**

This Timestamp header field contains the time a message was created.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## ClearBody method

Clears the body of the message.

### Prototypes

```
' Visual Basic
Public Sub ClearBody()

// C#
public void ClearBody();
```

## ClearProperties method

Clears all the properties of the message.

### Prototypes

```
' Visual Basic
Public Sub ClearProperties()

// C#
public void ClearProperties();
```

## GetBooleanProperty method

Gets a boolean message property.

### Prototypes

```
' Visual Basic
Public Function GetBooleanProperty( _
    ByVal propName As String _
) As Boolean

// C#
public bool GetBooleanProperty(
    string propName
);
```

### Parameters

◆ **propName** The property name.

### Return value

The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

## See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## GetByteProperty method

Gets a byte message property.

## Prototypes

```
' Visual Basic
Public Function GetByteProperty( _
    ByVal propName As String _
) As Byte

// C#
public byte GetByteProperty(
    string propName
);
```

## Parameters

- ◆ **propName** The property name.

## Return value

The property value.

## Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

## See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## GetDoubleProperty method

Gets a double message property.

## Prototypes

```
' Visual Basic
Public Function GetDoubleProperty( _
    ByVal propName As String _
) As Double

// C#
public double GetDoubleProperty(
    string propName
);
```

## Parameters

- ◆ **propName** The property name.

## Return value

The property value.

## Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

## See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## GetFloatProperty method

Gets a float message property.

## Prototypes

```
' Visual Basic
Public Function GetFloatProperty( _
    ByVal propName As String _
) As Single

// C#
public float GetFloatProperty(
    string propName
);
```

## Parameters

- ◆ **propName** The property name.

**Return value**

The property value.

**Remarks**

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**Exceptions**

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

**See also**

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

**GetIntProperty method**

Gets an int message property.

**Prototypes**

```
' Visual Basic
Public Function GetIntProperty( _
    ByVal propName As String _
) As Integer
```

```
// C#
public int GetIntProperty(
    string propName
);
```

**Parameters**

- ◆ **propName** The property name.

**Return value**

The property value.

**Remarks**

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**Exceptions**

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

**See also**

- ◆ [“QAMessage interface” on page 314](#)

- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## GetLongProperty method

Gets a long message property.

### Prototypes

```
' Visual Basic
Public Function GetLongProperty( _
    ByVal propName As String _
) As Long

// C#
public long GetLongProperty(
    string propName
);
```

### Parameters

- ◆ **propName** The property name.

### Return value

The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

### See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## GetProperty method

Gets a message property.

### Prototypes

```
' Visual Basic
Public Function GetProperty( _
    ByVal propName As String _
) As Object
```

```
// C#  
public object GetProperty(  
    string propName  
);
```

### Parameters

◆ **propName** The property name.

### Return value

The property value.

### Remarks

The property must be one of the acceptable primitive types, string, or DateTime.

### Exceptions

◆ [QAException class](#) - Thrown if the property does not exist.

## GetPropertyNames method

Gets an enumerator over the property names of the message.

### Prototypes

```
' Visual Basic  
Public Function GetPropertyNames() As System.Collections.IEnumerator
```

```
// C#  
public System.Collections.IEnumerator GetPropertyNames();
```

### Return value

An enumerator over the message property names.

## GetPropertyType method

Returns the property type of the given property.

### Prototypes

```
' Visual Basic  
Public Function GetPropertyType( _  
    ByVal propName As String _  
) As PropertyType
```

```
// C#  
public PropertyType GetPropertyType(  
    string propName  
);
```

### Parameters

◆ **propName** The name of the property.

## Return value

The property type.

## GetSbyteProperty method

Gets a signed byte message property.

### Prototypes

#### ' Visual Basic

```
Public Function GetSbyteProperty( _  
    ByVal propName As String _  
) As System.SByte
```

#### // C#

```
public System.Sbyte GetSbyteProperty(  
    string propName  
);
```

### Parameters

- ◆ **propName** the property name.

### Return value

The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

### See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## GetShortProperty method

Gets a short message property.

### Prototypes

#### ' Visual Basic

```
Public Function GetShortProperty( _  
    ByVal propName As String _  
) As Short
```

```
// C#
public short GetShortProperty(
    string propName
);
```

### Parameters

- ◆ **propName** The property name.

### Return value

The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### Exceptions

- ◆ [QAEException class](#) - Thrown if there is a conversion error getting the property value or if the property does not exist.

### See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## GetStringProperty method

Gets a string message property.

### Prototypes

```
' Visual Basic
Public Function GetStringProperty( _
    ByVal propName As String _
) As String
```

```
// C#
public string GetStringProperty(
    string propName
);
```

### Parameters

- ◆ **propName** The property name.

### Return value

The property value or null if the property does not exist.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

### PropertyExists method

Indicates whether the given property has been set for this message.

#### Prototypes

```
' Visual Basic
Public Function PropertyExists( _
    ByVal propName As String _
) As Boolean
```

```
// C#
public bool PropertyExists(
    string propName
);
```

#### Parameters

- ◆ **propName** The property name.

#### Return value

True if the property exists.

### SetBooleanProperty method

Sets a boolean property.

#### Prototypes

```
' Visual Basic
Public Sub SetBooleanProperty( _
    ByVal propName As String, _
    ByVal val As Boolean _
)
```

```
// C#
public void SetBooleanProperty(
    string propName,
    bool val
);
```

#### Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

## Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## SetByteProperty method

Sets a byte property.

## Prototypes

```
' Visual Basic
Public Sub SetByteProperty( _
    ByVal propName As String, _
    ByVal val As Byte _
)
```

```
// C#
public void SetByteProperty(
    string propName,
    byte val
);
```

## Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

## Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## SetDoubleProperty method

Sets a double property.

## Prototypes

```
' Visual Basic
Public Sub SetDoubleProperty( _
    ByVal propName As String, _
```

```
    ByVal val As Double _  
)
```

```
// C#  
public void SetDoubleProperty(  
    string propName,  
    double val  
);
```

### Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## SetFloatProperty method

Sets a float property.

### Prototypes

```
' Visual Basic  
Public Sub SetFloatProperty( _  
    ByVal propName As String, _  
    ByVal val As Single _  
)
```

```
// C#  
public void SetFloatProperty(  
    string propName,  
    float val  
);
```

### Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See also**

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

**SetIntProperty method**

Sets an int property.

**Prototypes**

```
' Visual Basic
Public Sub SetIntProperty( _
    ByVal propName As String, _
    ByVal val As Integer _
)

// C#
public void SetIntProperty(
    string propName,
    int val
);
```

**Parameters**

- ◆ **propName** The property name.
- ◆ **val** The property value.

**Remarks**

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See also**

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

**SetLongProperty method**

Sets a long property.

**Prototypes**

```
' Visual Basic
Public Sub SetLongProperty( _
    ByVal propName As String, _
    ByVal val As Long _
)
```

```
// C#  
public void SetLongProperty(  
    string propName,  
    long val  
);
```

#### Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

#### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

#### See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## SetProperty method

Sets a property.

#### Prototypes

```
' Visual Basic  
Public Sub SetProperty( _  
    ByVal propName As String, _  
    ByVal val As Object _  
)
```

```
// C#  
public void SetProperty(  
    string propName,  
    object val  
);
```

#### Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

#### Remarks

The property type must be one of the acceptable primitive types, or String.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

#### See also

- ◆ [“QAMessage interface” on page 314](#)

- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## SetSbyteProperty method

Sets a signed byte property.

### Prototypes

```
' Visual Basic
Public Sub SetSbyteProperty( _
    ByVal propName As String, _
    ByVal val As System.SByte _
)

// C#
public void SetSbyteProperty(
    string propName,
    System.Sbyte val
);
```

### Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See also

- ◆ [“QAMessage interface” on page 314](#)
- ◆ [“QAMessage members” on page 315](#)
- ◆ [“MessageProperties class” on page 245](#)

## SetShortProperty method

Sets a short property.

### Prototypes

```
' Visual Basic
Public Sub SetShortProperty( _
    ByVal propName As String, _
    ByVal val As Short _
)

// C#
public void SetShortProperty(
    string propName,
```

```
    short val  
);
```

### Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties”](#) on page 206.

### See also

- ◆ [“QAMessage interface”](#) on page 314
- ◆ [“QAMessage members”](#) on page 315
- ◆ [“MessageProperties class”](#) on page 245

## SetStringProperty method

Sets a string property.

### Prototypes

#### ' Visual Basic

```
Public Sub SetStringProperty( _  
    ByVal propName As String, _  
    ByVal val As String _  
)
```

#### // C#

```
public void SetStringProperty(  
    string propName,  
    string val  
);
```

### Parameters

- ◆ **propName** The property name.
- ◆ **val** The property value.

### Remarks

For more information about getting and setting message headers and properties, see [“Message headers and message properties”](#) on page 206.

### See also

- ◆ [“QAMessage interface”](#) on page 314
- ◆ [“QAMessage members”](#) on page 315
- ◆ [“MessageProperties class”](#) on page 245

## QATextMessage interface

QATextMessage inherits from the [QAMessage interface](#) class and adds a text message body. QATextMessage provides methods to read from and write to the text message body.

### Prototypes

```
' Visual Basic
Public Interface QATextMessage
```

```
// C#
public interface QATextMessage
```

### Remarks

When the message is first created, the body of the message is in write-only mode. After a message has been sent, the client that sent it can retain and modify it without affecting the message that has been sent. The same message object can be sent multiple times.

When a message is received, the provider has called [Reset method](#) so that the message body is in read-only mode and reading of values starts from the beginning of the message body.

### See also

- ◆ [“QATextMessage members” on page 335](#)
- ◆ [“QABinaryMessage interface” on page 255](#)

## QATextMessage members

### Public properties

Member name	Description
<a href="#">Text property</a>	The message text.
<a href="#">TextLength property</a>	The length, in characters, of the message.

### Public methods

Member name	Description
<a href="#">ReadText method</a>	Read unread text into the given buffer.
<a href="#">Reset method</a>	Resets the text position of the message to the beginning.
<a href="#">WriteText method</a>	Append text to the text of the message.

### Text property

The message text.

## Prototypes

```
' Visual Basic  
Public Property Text As String
```

```
// C#  
public string Text {get;set;}
```

## Remarks

If the message exceeds the maximum size specified by the QAManager `MAX_IN_MEMORY_MESSAGE_SIZE`, this property is null. In this case, use the [ReadText method](#) to read the text.

For more information about QAManager properties, see “[QAnywhere manager configuration properties](#)” on page 62.

## TextLength property

The length, in characters, of the message.

## Prototypes

```
' Visual Basic  
Public Readonly Property TextLength As Long
```

```
// C#  
public long TextLength {get;}
```

## ReadText method

Read unread text into the given buffer.

## Prototypes

```
' Visual Basic  
Public Function ReadText( _  
    ByVal buf As System.Text.StringBuilder _  
) As Integer
```

```
// C#  
public int ReadText(  
    System.Text.string Builder buf  
);
```

## Parameters

◆ **buf** Target buffer for any read text.

## Return value

The number of characters read or -1 if there are no more characters to read.

## Remarks

Any additional unread text must be read by subsequent calls to this method. Text is read from the beginning of any unread text.

## Reset method

Resets the text position of the message to the beginning.

## Prototypes

```
' Visual Basic
Public Sub Reset()

// C#
public void Reset();
```

## WriteText method

Append text to the text of the message.

## Prototypes

```
' Visual Basic
Public Sub WriteText( _
    ByVal val As String _
)

// C#
public void WriteText(
    string val
);
```

## Parameters

◆ **val** The text to append.

## QATransactionalManager interface

The QATransactionalManager class derives from [QAManagerBase interface](#) and manages transactional QAnywhere messaging operations.

## Prototypes

```
' Visual Basic
Public Interface QATransactionalManager

// C#
public interface QATransactionalManager
```

## Remarks

For a detailed description of derived behavior, see [QAManagerBase interface](#).

The QATransactionalManager can only be used for transactional acknowledgement. Use the [Commit method](#) to commit all [PutMessage method](#) and [GetMessage method](#) invocations.

For more information, see “[Implementing transactional messaging](#)” on page 68.

**See also**

- ◆ “[QATransactionalManager members](#)” on page 338
- ◆ “[QATransactionalManager interface](#)” on page 337

**QATransactionalManager members****Public methods**

Member name	Description
<a href="#">Commit method</a>	Commits the current transaction and begins a new transaction.
<a href="#">Open method</a>	Opens a QATransactionalManager instance.
<a href="#">Rollback method</a>	Rolls back the current transaction and begins a new transaction.

**Commit method**

Commits the current transaction and begins a new transaction.

**Prototypes**

```
' Visual Basic  
Public Sub Commit()
```

```
// C#  
public void Commit();
```

**Remarks**

This method commits all [PutMessage method](#) and [GetMessage method](#) invocations. *Note:* The first transaction begins with the call to [Open method](#).

**Exceptions**

- ◆ [QAException class](#) - Thrown if there is a problem committing.

**See also**

- ◆ “[QATransactionalManager interface](#)” on page 337
- ◆ “[QATransactionalManager members](#)” on page 338
- ◆ “[QATransactionalManager interface](#)” on page 337

## Open method

Opens a QATransactionalManager instance.

### Prototypes

```
' Visual Basic  
Public Sub Open()
```

```
// C#  
public void Open();
```

### Remarks

The Open method must be the first method called after creating a manager.

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem opening the manager

### See also

- ◆ [“QATransactionalManager interface” on page 337](#)
- ◆ [“QATransactionalManager members” on page 338](#)
- ◆ [“QATransactionalManager interface” on page 337](#)

## Rollback method

Rolls back the current transaction and begins a new transaction.

### Prototypes

```
' Visual Basic  
Public Sub Rollback()
```

```
// C#  
public void Rollback();
```

### Remarks

This method rolls back all uncommitted [PutMessage method](#) and [GetMessage method](#) invocations.

### Exceptions

- ◆ [QAException class](#) - Thrown if there is a problem rolling back

### See also

- ◆ [“QATransactionalManager interface” on page 337](#)
- ◆ [“QATransactionalManager members” on page 338](#)
- ◆ [“QATransactionalManager interface” on page 337](#)

## QueueDepthFilter enumeration

Provides queue depth filter values for [GetQueueDepth method](#) and [GetQueueDepth method](#).

### Prototypes

```
' Visual Basic  
Public Enum QueueDepthFilter
```

```
// C#  
public enum QueueDepthFilter
```

### Member name

Member name	Description
ALL	Count both incoming and outgoing messages. System messages and expired messages are not included in any queue depth counts.
INCOMING	Count only incoming messages. An incoming message is defined as a message whose originator is different than the agent ID of the message store.
OUTGOING	Count only outgoing messages. An outgoing message is defined as a message whose originator is the agent ID of the message store, and whose destination is not the agent ID of the message store.

## StatusCodes enumeration

This enumeration defines a set of codes for the status of a message.

### Prototypes

```
' Visual Basic  
Public Enum StatusCodes
```

```
// C#  
public enum StatusCodes
```

### Member name

Member name	Description
CANCELLED	The message has been cancelled. This code applies to the MessageProperties.STATUS.
EXPIRED	The message has expired because it was not received before its expiration time had passed. This code applies to the MessageProperties.STATUS.
FINAL	The message has achieved a final state. This code applies to the MessageProperties.STATUS.

<b>Member name</b>	<b>Description</b>
LOCAL	The message is addressed to the local message store and will not be transmitted to the server. This code applies to the MessageProperties.TRANSMISSION_STATUS.
PENDING	The message has been sent but not received. This code applies to the MessageProperties.STATUS.
RECEIVED	The message has been received and acknowledged by the receiver. This code applies to the MessageProperties.STATUS.
RECEIVING	The message is in the process of being received, or it was received but not acknowledged. This code applies to the MessageProperties.STATUS.
TRANSMITTED	The message has been transmitted to the server. This code applies to the MessageProperties.TRANSMISSION_STATUS.
TRANSMITTING	The message is in the process of being transmitted to the server. This code applies to the MessageProperties.TRANSMISSION_STATUS.
UNRECEIVABLE	The message has been marked as unreceivable. The message is either malformed, or there were too many failed attempts to deliver it. This code applies to the MessageProperties.STATUS.
UNTRANSMITTED	The message has not been transmitted to the server. This code applies to the MessageProperties.TRANSMISSION_STATUS.

## iAnywhere.QAnywhere.WS namespace (.NET )

The iAnywhere.QAnywhere.WS namespace contains classes and enumerations for building applications that handle messaging between QAnywhere and mobile web services.

### WSBase class

This is the base class for the main web service proxy class generated by the mobile web service compiler.

#### Prototypes

```
' Visual Basic
Public Class WSBase
```

```
// C#
public class WSBase
```

### WSBase members

#### Public constructors

Member name	Description
<a href="#">WSBase constructor</a>	Constructs a WSBase instance with the properties specified by a configuration property file.
<a href="#">WSBase constructor</a>	Constructs a WSBase instance with default properties.

#### Public methods

Member name	Description
<a href="#">ClearRequestProperties method</a>	Clears all request properties that have been set for this WSBase.
<a href="#">GetResult method</a>	Gets a WSResult object that represents the results of a web service request.
<a href="#">GetServiceID method</a>	Gets the service ID for this instance of WSBase.
<a href="#">SetListener method</a>	Sets a listener for the results of a given web service request.
<a href="#">SetListener method</a>	Sets a listener for the results of all web service requests made by this instance of WSBase.
<a href="#">SetProperty method</a>	Sets a configuration property for this instance of WSBase.
<a href="#">SetQAManager method</a>	Sets the QAManagerBase that is used by this web service client to do web service requests.
<a href="#">SetRequestProperty method</a>	Sets a request property for webservice requests made by this WSBase.

Member name	Description
<a href="#">SetServiceID method</a>	Sets a user-defined ID for this instance of WSBase.

## WSBase constructor

Constructs a WSBase instance with the properties specified by a configuration property file.

### Prototypes

```
' Visual Basic
Overloads Public Sub New( _
    ByVal iniFile As String _
)
```

```
// C#
public WSBase(
    string iniFile
);
```

### Parameters

- ◆ **iniFile** A file containing configuration properties.

### Remarks

Valid configuration properties are:

LOG\_FILE a file to which to log runtime information.

LOG\_LEVEL a value between 0 and 6 that controls the verbosity of information logged, with 6 being the highest verbosity.

WS\_CONNECTOR\_ADDRESS the address of the web service connector in the MobiLink server.

The default WS\_CONNECTOR\_ADDRESS is "iAnywhere.connector.webservices\\".

### Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem constructing the WSBase.

## WSBase constructor

Constructs a WSBase instance with default properties.

### Prototypes

```
' Visual Basic
Overloads Public Sub New()
```

```
// C#
public WSBase();
```

## Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem constructing the WSBase.

## ClearRequestProperties method

Clears all request properties that have been set for this WSBase.

### Prototypes

```
' Visual Basic
Public Sub ClearRequestProperties()

// C#
public void ClearRequestProperties();
```

## GetResult method

Gets a WSResult object that represents the results of a web service request.

### Prototypes

```
' Visual Basic
Public Function GetResult( _
    ByVal requestID As String _
) As iAnywhere.QAnywhere.WS.WSResult

// C#
public iAnywhere.QAnywhere.WS.WSResult GetResult(
    string requestID
);
```

### Parameters

- ◆ **requestID** The ID of the web service request.

### Return value

A WSResult instance representing the results of the web service request.

### See also

- ◆ [“WSBase class” on page 342](#)
- ◆ [“WSBase members” on page 342](#)
- ◆ [“WSStatus enumeration” on page 388](#)

## GetServiceID method

Gets the service ID for this instance of WSBase.

### Prototypes

```
' Visual Basic
Public Function GetServiceID() As String
```

```
// C#  
public string GetServiceID();
```

### Return value

The service ID.

### SetListener method

Sets a listener for the results of a given web service request.

### Prototypes

```
' Visual Basic  
Overloads Public Sub SetListener( _  
    ByVal requestID As String, _  
    ByVal listener As iAnywhere.QAnywhere.WS.WSListener _  
)  
  
// C#  
public void SetListener(  
    string requestID,  
    iAnywhere.QAnywhere.WS.WSListener listener  
);
```

### Parameters

- ◆ **requestID** The ID of the web service request to which to listen for results.
- ◆ **listener** The listener object that gets called when the result of the given web service request is available.

### Remarks

Listeners are typically used to get results of the *asyncXYZ* methods of the service.

To remove a listener, call `SetListener` with null as the listener.

*Note:* This method replaces the listener set by any previous call to `SetListener`.

### SetListener method

Sets a listener for the results of all web service requests made by this instance of `WSBase`.

### Prototypes

```
' Visual Basic  
Overloads Public Sub SetListener( _  
    ByVal listener As iAnywhere.QAnywhere.WS.WSListener _  
)  
  
// C#  
public void SetListener(  
    iAnywhere.QAnywhere.WS.WSListener listener  
);
```

**Parameters**

- ◆ **listener** The listener object that gets called when the result of a web service request is available.

**Remarks**

Listeners are typically used to get results of the asyncXYZ methods of the service.

To remove a listener, call `SetListener` with null as the listener.

*Note:* This method replaces the listener set by any previous call to `SetListener`.

**SetProperty method**

Sets a configuration property for this instance of `WSBase`.

**Prototypes**

```
' Visual Basic
Public Sub SetProperty( _
    ByVal property As String, _
    ByVal val As String _
)

// C#
public void SetProperty(
    string property,
    string val
);
```

**Parameters**

- ◆ **property** The property name to set.
- ◆ **val** The property value.

**Remarks**

Configuration properties must be set before any asynchronous or synchronous web service request is made. This method has no effect if it is called after a web service request has been made.

Valid configuration properties are:

`LOG_FILE` a file to which to log runtime information.

`LOG_LEVEL` a value between 0 and 6 that controls the verbosity of information logged, with 6 being the highest verbosity.

`WS_CONNECTOR_ADDRESS` the address of the web service connector in the MobiLink server. The default is: "iAnywhere.connector.webservices\\".

**SetQAManager method**

Sets the `QAManagerBase` that is used by this web service client to do web service requests.

## Prototypes

```
' Visual Basic
Public Sub SetQAManager( _
    ByVal mgr As QAManagerBase _
)

// C#
public void SetQAManager(
    QAManagerBase mgr
);
```

## Parameters

◆ **mgr** The QAManagerBase to use.

## Remarks

*Note:* If you use an EXPLICIT\_ACKNOWLEDGEMENT QAManager, you can acknowledge the result of an asynchronous web service request by calling the acknowledge() method of WSResult. The result of a synchronous web service request is automatically acknowledged, even in the case of an EXPLICIT\_ACKNOWLEDGEMENT QAManager. If you use an IMPLICIT\_ACKNOWLEDGEMENT QAManager, the result of any web service request is acknowledged automatically.

## SetRequestProperty method

Sets a request property for webservice requests made by this WSBase.

## Prototypes

```
' Visual Basic
Public Sub SetRequestProperty( _
    ByVal name As String, _
    ByVal value As Object _
)

// C#
public void SetRequestProperty(
    string name,
    object value
);
```

## Parameters

◆ **name** The property name to set.

◆ **value** The property value.

## Remarks

A request property is set on each QAMessage that is sent by this WSBase, until the property is cleared. A request property is cleared by setting it to a null value. The type of the message property is determined by the class of the value parameter. For example, if value is an instance of Int32, then SetIntProperty is used to set the property on the QAMessage.

## SetServiceID method

Sets a user-defined ID for this instance of WSBase.

### Prototypes

```
' Visual Basic
Public Sub SetServiceID( _
    ByVal serviceID As String _
)

// C#
public void SetServiceID(
    string serviceID
);
```

### Parameters

- ◆ **serviceID** The service ID.

### Remarks

The service ID should be set to a value unique to this instance of WSBase. It is used internally to form a queue name for sending and receiving web service requests. Therefore, the service ID should be persisted between application sessions, in order to retrieve results of web service requests made in a previous session.

## WSEException class

This class represents an exception that occurred during processing of a web service request.

### Prototypes

```
' Visual Basic
Public Class WSEException
    Inherits Exception

// C#
public class WSEException :
    Exception
```

### WSEException members

#### Public static fields (shared)

Member name	Description
<a href="#">WS_STATUS_HTTP_ERROR field</a>	Error code indicating that there was an error in the web service HTTP request made by the web services connector.
<a href="#">WS_STATUS_HTTP_OK field</a>	Error code indicating that the webservice HTTP request by the web services connector was successful.

Member name	Description
<a href="#">WS_STATUS_HTTP_RETRIES_EXCEEDED</a> field	Error code indicating that the number of HTTP retries was exceeded the web services connector.
<a href="#">WS_STATUS_SOAP_PARSE_ERROR</a> field	Error code indicating that there was an error in the web services runtime or in the webservices connector in parsing a SOAP response or request.

**Public constructors**

Member name	Description
<a href="#">WSException</a> constructor	Constructs a new exception with the specified error message.
<a href="#">WSException</a> constructor	Constructs a new exception with the specified error message and error code.
<a href="#">WSException</a> constructor	Constructs a new exception.

**Public properties**

Member name	Description
<a href="#">ErrorCode</a> property	The error code associated with this exception.
<a href="#">HelpLink</a> (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
<a href="#">InnerException</a> (inherited from Exception)	Gets the <a href="#">System.Exception</a> instance that caused the current exception.
<a href="#">Message</a> (inherited from Exception)	Gets a message that describes the current exception.
<a href="#">Source</a> (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
<a href="#">StackTrace</a> (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
<a href="#">TargetSite</a> (inherited from Exception)	Gets the method that throws the current exception.

**Public methods**

Member name	Description
<a href="#">GetBaseException</a> (inherited from Exception)	When overridden in a derived class, returns the <a href="#">System.Exception</a> that is the root cause of one or more subsequent exceptions.

Member name	Description
<a href="#">GetObjectData</a> (inherited from Exception)	When overridden in a derived class, sets the <a href="#">System.Runtime.Serialization.SerializationInfo</a> with information about the exception.
<a href="#">ToString</a> (inherited from Exception)	Creates and returns a string representation of the current exception.

## WSException constructor

Constructs a new exception with the specified error message.

### Prototypes

```
' Visual Basic  
Overloads Public Sub New( _  
    ByVal msg As String _  
)
```

```
// C#  
public WSException(  
    string msg  
);
```

### Parameters

◆ **msg** The error message.

## WSException constructor

Constructs a new exception with the specified error message and error code.

### Prototypes

```
' Visual Basic  
Overloads Public Sub New( _  
    ByVal msg As String, _  
    ByVal errorCode As Integer _  
)
```

```
// C#  
public WSException(  
    string msg,  
    int errorCode  
);
```

### Parameters

◆ **msg** The error message.

◆ **errorCode** The error code.

## WSEException constructor

Constructs a new exception.

### Prototypes

```
' Visual Basic
Overloads Public Sub New( _
    ByVal ex As System.Exception _
)

// C#
public WSEException(
    System.Exception ex
);
```

### Parameters

◆ **ex** The exception.

## WS\_STATUS\_HTTP\_ERROR field

Error code indicating that there was an error in the web service HTTP request made by the web services connector.

### Prototypes

```
' Visual Basic
Public Shared WS_STATUS_HTTP_ERROR As Integer

// C#
public const int WS_STATUS_HTTP_ERROR;
```

## WS\_STATUS\_HTTP\_OK field

Error code indicating that the webservice HTTP request by the web services connector was successful.

### Prototypes

```
' Visual Basic
Public Shared WS_STATUS_HTTP_OK As Integer

// C#
public const int WS_STATUS_HTTP_OK;
```

## WS\_STATUS\_HTTP\_RETRIES\_EXCEEDED field

Error code indicating that the number of HTTP retries was exceeded the web services connector.

### Prototypes

```
' Visual Basic
Public Shared WS_STATUS_HTTP_RETRIES_EXCEEDED As Integer
```

```
// C#
public const int WS_STATUS_HTTP_RETRIES_EXCEEDED;
```

### WS\_STATUS\_SOAP\_PARSE\_ERROR field

Error code indicating that there was an error in the web services runtime or in the webservices connector in parsing a SOAP response or request.

#### Prototypes

```
' Visual Basic
Public Shared WS_STATUS_SOAP_PARSE_ERROR As Integer
```

```
// C#
public const int WS_STATUS_SOAP_PARSE_ERROR;
```

### ErrorCode property

The error code associated with this exception.

#### Prototypes

```
' Visual Basic
Public Property ErrorCode As Integer
```

```
// C#
public int ErrorCode {get;set;}
```

### WSFaultException class

This class represents a SOAP Fault exception from the web service connector.

#### Prototypes

```
' Visual Basic
Public Class WSFaultException
    Inherits WSException
```

```
// C#
public class WSFaultException :
    WSException
```

### WSFaultException members

#### Public constructors

Member name	Description
<a href="#">WSFaultException constructor</a>	Constructs a new exception with the specified error message.

**Public properties**

Member name	Description
<a href="#">ErrorCode</a> property (inherited from WSException)	The error code associated with this exception.
<a href="#">HelpLink</a> (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
<a href="#">InnerException</a> (inherited from Exception)	Gets the <a href="#">System.Exception</a> instance that caused the current exception.
<a href="#">Message</a> (inherited from Exception)	Gets a message that describes the current exception.
<a href="#">Source</a> (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
<a href="#">StackTrace</a> (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
<a href="#">TargetSite</a> (inherited from Exception)	Gets the method that throws the current exception.

**Public methods**

Member name	Description
<a href="#">GetBaseException</a> (inherited from Exception)	When overridden in a derived class, returns the <a href="#">System.Exception</a> that is the root cause of one or more subsequent exceptions.
<a href="#">GetObjectData</a> (inherited from Exception)	When overridden in a derived class, sets the <a href="#">System.Runtime.Serialization.SerializationInfo</a> with information about the exception.
<a href="#">ToString</a> (inherited from Exception)	Creates and returns a string representation of the current exception.

**WSFaultException constructor**

Constructs a new exception with the specified error message.

**Prototypes**

```
' Visual Basic
Public Sub New( _
    ByVal msg As String _
)
```

```
// C#
public WSFaultException(
    string msg
);
```

**Parameters**

- ◆ **msg** The error message.

**WSListener interface**

This class represents a listener for results of web service requests.

**Prototypes**

```
' Visual Basic
Public Interface WSListener
```

```
// C#
public interface WSListener
```

**WSListener members**

**Public methods**

Member name	Description
<a href="#">OnException method</a>	Called when an exception occurs during processing of the result of an asynchronous web service request.
<a href="#">OnResult method</a>	Called with the result of an asynchronous web service request.

**OnException method**

Called when an exception occurs during processing of the result of an asynchronous web service request.

**Prototypes**

```
' Visual Basic
Public Sub OnException( _
    ByVal e As iAnywhere.QAnywhere.WS.WSException, _
    ByVal wsResult As iAnywhere.QAnywhere.WS.WSResult _
)
```

```
// C#
public void OnException(
    iAnywhere.QAnywhere.WS.WSException e,
    iAnywhere.QAnywhere.WS.WSResult wsResult
);
```

**Parameters**

- ◆ **e** The WSException that occurred during processing of the result.
- ◆ **wsResult** A WSResult, from which the request ID may be obtained. Values of this WSResult are not defined.

## OnResult method

Called with the result of an asynchronous web service request.

### Prototypes

```
' Visual Basic
Public Sub OnResult( _
    ByVal wsResult As iAnywhere.QAnywhere.WS.WSResult _
)

// C#
public void OnResult(
    iAnywhere.QAnywhere.WS.WSResult wsResult
);
```

### Parameters

- ◆ **wsResult** The WSResult describing the result of a web service request.

## WSResult class

This class represents the results of a web service request.

### Prototypes

```
' Visual Basic
Public Class WSResult

// C#
public class WSResult
```

### Remarks

A WSResult object is obtained in one of three ways:

- It is passed to the WSListener.onResult.
- It is returned by an asyncXYZ method of the service proxy generated by the compiler.
- It is obtained by calling WSBase.getResult with a specific request ID.

## WSResult members

### Public methods

Member name	Description
<a href="#">Acknowledge method</a>	Acknowledges that this WSResult has been processed.
<a href="#">GetArrayValue method</a>	Gets an array of complex types value from this WSResult.
<a href="#">GetBoolArrayValue method</a>	Gets an array of bool values from this WSResult.

<b>Member name</b>	<b>Description</b>
<a href="#">GetBooleanArrayValue method</a>	Gets an array of Boolean values from this WSResult.
<a href="#">GetBooleanValue method</a>	Gets a Boolean value from this WSResult.
<a href="#">GetBoolValue method</a>	Gets a bool value from this WSResult.
<a href="#">GetByteArrayValue method</a>	Gets an array of byte values from this WSResult.
<a href="#">GetByteValue method</a>	Gets a byte value from this WSResult.
<a href="#">GetCharArrayValue method</a>	Gets an array of char values from this WSResult.
<a href="#">GetCharValue method</a>	Gets a char value from this WSResult.
<a href="#">GetDecimalArrayValue method</a>	Gets an array of decimal values from this WSResult.
<a href="#">GetDecimalValue method</a>	Gets a decimal value from this WSResult.
<a href="#">GetDoubleArrayValue method</a>	Gets an array of double values from this WSResult.
<a href="#">GetDoubleValue method</a>	Gets a double value from this WSResult.
<a href="#">GetErrorMessage method</a>	Gets the error message.
<a href="#">GetFloatArrayValue method</a>	Gets an array of float values from this WSResult.
<a href="#">GetFloatValue method</a>	Gets a float value from this WSResult.
<a href="#">GetInt16ArrayValue method</a>	Gets an array of Int16 values from this WSResult.
<a href="#">GetInt16Value method</a>	Gets an Int16 value from this WSResult.
<a href="#">GetInt32ArrayValue method</a>	Gets an array of Int32 values from this WSResult.
<a href="#">GetInt32Value method</a>	Gets an Int32 value from this WSResult.
<a href="#">GetInt64ArrayValue method</a>	Gets an array of Int64 values from this WSResult.
<a href="#">GetInt64Value method</a>	Gets an Int64 value from this WSResult.
<a href="#">GetIntArrayValue method</a>	Gets an array of int values from this WSResult.
<a href="#">GetIntValue method</a>	Gets an int value from this WSResult.
<a href="#">GetLongArrayValue method</a>	Gets an array of long values from this WSResult.
<a href="#">GetLongValue method</a>	Gets a long value from this WSResult.
<a href="#">GetNullableBoolArrayValue method</a>	Gets an array of bool values from this WSResult.
<a href="#">GetNullableBoolValue method</a>	Gets a bool value from this WSResult.

<b>Member name</b>	<b>Description</b>
<a href="#">GetNullableDoubleArrayValue method</a>	Gets an array of double values from this WSResult.
<a href="#">GetNullableDoubleValue method</a>	Gets a double value from this WSResult.
<a href="#">GetNullableFloatArrayValue method</a>	Gets an array of float values from this WSResult.
<a href="#">GetNullableFloatValue method</a>	Gets a float value from this WSResult.
<a href="#">GetNullableIntArrayValue method</a>	Gets an array of int values from this WSResult.
<a href="#">GetNullableIntValue method</a>	Gets an int value from this WSResult.
<a href="#">GetNullableLongArrayValue method</a>	Gets an array of long values from this WSResult.
<a href="#">GetNullableLongValue method</a>	Gets an Int64 value from this WSResult.
<a href="#">GetNullableSByteArrayValue method</a>	Gets an array of byte values from this WSResult.
<a href="#">GetNullableSByteValue method</a>	Gets a byte value from this WSResult.
<a href="#">GetNullableShortArrayValue method</a>	Gets an array of short values from this WSResult.
<a href="#">GetNullableShortValue method</a>	Gets a short value from this WSResult.
<a href="#">GetObjectArrayValue method</a>	Gets an array of Object values from this WSResult.
<a href="#">GetObjectValue method</a>	Gets an object value from this WSResult.
<a href="#">GetRequestID method</a>	Gets the request ID that this WSResult represents.
<a href="#">GetSByteArrayValue method</a>	Gets an array of sbyte values from this WSResult.
<a href="#">GetSByteValue method</a>	Gets an sbyte value from this WSResult.
<a href="#">GetSByteValue method</a>	Gets an sbyte value from this WSResult.
<a href="#">GetShortArrayValue method</a>	Gets an array of short values from this WSResult.
<a href="#">GetShortValue method</a>	Gets a short value from this WSResult.
<a href="#">GetSingleArrayValue method</a>	Gets an array of Single values from this WSResult.
<a href="#">GetSingleValue method</a>	Gets a Single value from this WSResult.
<a href="#">GetStatus method</a>	Gets the status of this WSResult.

Member name	Description
<a href="#">GetStringArrayValue method</a>	Gets an array of string values from this WSResult.
<a href="#">GetStringValue method</a>	Gets a string value from this WSResult.
<a href="#">GetUIntArrayValue method</a>	Gets an array of unsigned int values from this WSResult.
<a href="#">GetUIntValue method</a>	Gets a unsigned int value from this WSResult.
<a href="#">GetULongArrayValue method</a>	Gets an array of unsigned long values from this WSResult.
<a href="#">GetULongValue method</a>	Gets a unsigned long value from this WSResult.
<a href="#">GetUShortArrayValue method</a>	Gets an array of unsigned short values from this WSResult.
<a href="#">GetUShortValue method</a>	Gets a unsigned short value from this WSResult.
<a href="#">GetValue method</a>	Gets the value of a complex type from this WSResult.
<a href="#">SetLogger method</a>	Turns debug on or off.

## Acknowledge method

Acknowledges that this WSResult has been processed.

### Prototypes

```
' Visual Basic  
Public Sub Acknowledge()
```

```
// C#  
public void Acknowledge();
```

### Remarks

This method is only useful when an EXPLICIT\_ACKNOWLEDGEMENT QAManager is being used.

## GetArrayValue method

Gets an array of complex types value from this WSResult.

### Prototypes

```
' Visual Basic  
Public Function GetArrayValue( _  
    ByVal parentName As String _  
) As iAnywhere.QAnywhere.WS.WSSerializable()
```

```
// C#  
public iAnywhere.QAnywhere.WS.WSSerializable[] GetArrayValue(  
    string parentName  
);
```

**Parameters**

- ◆ **parentName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetBoolArrayValue method**

Gets an array of bool values from this WSResult.

**Prototypes**

```
' Visual Basic
Public Function GetBoolArrayValue( _
    ByVal elementName As String _
) As Boolean()
```

```
// C#
public bool[] GetBoolArrayValue(
    string elementName
);
```

**Parameters**

- ◆ **elementName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetBooleanArrayValue method**

Gets an array of Boolean values from this WSResult.

**Prototypes**

```
' Visual Basic
Public Function GetBooleanArrayValue( _
    ByVal elementName As String _
) As Boolean()
```

```
// C#
public bool[] GetBooleanArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetBooleanValue method

Gets a Boolean value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetBooleanValue( _
    ByVal childName As String _
) As Boolean
```

```
// C#
public bool GetBooleanValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetBoolValue method

Gets a bool value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetBoolValue( _
    ByVal childName As String _
) As Boolean
```

```
// C#
public bool GetBoolValue(
    string childName
);
```

**Parameters**

- ◆ **childName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetByteArrayValue method**

Gets an array of byte values from this WSResult.

**Prototypes**

```
' Visual Basic
Public Function GetByteArrayValue( _
    ByVal elementName As String _
) As Byte()
```

```
// C#
public byte[] GetByteArrayValue(
    string elementName
);
```

**Parameters**

- ◆ **elementName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetByteValue method**

Gets a byte value from this WSResult.

**Prototypes**

```
' Visual Basic
Public Function GetByteValue( _
    ByVal childName As String _
) As Byte
```

```
// C#
public byte GetByteValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetCharArrayValue method

Gets an array of char values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetCharArrayValue( _
    ByVal elementName As String _
) As Char()

// C#
public char[] GetCharArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetCharValue method

Gets a char value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetCharValue( _
    ByVal childName As String _
) As Char

// C#
public char GetCharValue(
    string childName
);
```

**Parameters**

- ◆ **childName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetDecimalArrayValue method**

Gets an array of decimal values from this WSResult.

**Prototypes**

```
' Visual Basic
Public Function GetDecimalArrayValue( _
    ByVal elementName As String _
) As Decimal()

// C#
public decimal[] GetDecimalArrayValue(
    string elementName
);
```

**Parameters**

- ◆ **elementName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetDecimalValue method**

Gets a decimal value from this WSResult.

**Prototypes**

```
' Visual Basic
Public Function GetDecimalValue( _
    ByVal childName As String _
) As Decimal

// C#
public decimal GetDecimalValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetDoubleArrayValue method

Gets an array of double values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetDoubleArrayValue( _
    ByVal elementName As String _
) As Double()

// C#
public double[] GetDoubleArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetDoubleValue method

Gets a double value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetDoubleValue( _
    ByVal childName As String _
) As Double

// C#
public double GetDoubleValue(
    string childName
);
```

**Parameters**

- ◆ **childName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetErrorMessage method**

Gets the error message.

**Prototypes**

```
' Visual Basic  
Public Function GetErrorMessage() As String
```

```
// C#  
public string GetErrorMessage();
```

**Return value**

The error message.

**GetFloatArrayValue method**

Gets an array of float values from this WSResult.

**Prototypes**

```
' Visual Basic  
Public Function GetFloatArrayValue( _  
    ByVal elementName As String _  
) As Single()
```

```
// C#  
public float [] GetFloatArrayValue(  
    string elementName  
);
```

**Parameters**

- ◆ **elementName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetFloatValue method

Gets a float value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetFloatValue( _
    ByVal childName As String _
) As Single

// C#
public float GetFloatValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetInt16ArrayValue method

Gets an array of Int16 values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetInt16ArrayValue( _
    ByVal elementName As String _
) As Short()

// C#
public short[] GetInt16ArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetInt16Value method

Gets an Int16 value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetInt16Value( _
    ByVal childName As String _
) As Short

// C#
public short GetInt16Value(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetInt32ArrayValue method

Gets an array of Int32 values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetInt32ArrayValue( _
    ByVal elementName As String _
) As Integer()

// C#
public int[] GetInt32ArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetInt32Value method

Gets an Int32 value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetInt32Value( _
    ByVal childName As String _
) As Integer

// C#
public int GetInt32Value(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetInt64ArrayValue method

Gets an array of Int64 values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetInt64ArrayValue( _
    ByVal elementName As String _
) As Long()

// C#
public long[] GetInt64ArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetInt64Value method

Gets an Int64 value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetInt64Value( _
    ByVal childName As String _
) As Long

// C#
public long GetInt64Value(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetIntArrayValue method

Gets an array of int values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetIntArrayValue( _
    ByVal elementName As String _
) As Integer()

// C#
public int[] GetIntArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetIntValue method

Gets an int value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetIntValue( _
    ByVal childName As String _
) As Integer

// C#
public int GetIntValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetLongArrayValue method

Gets an array of long values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetLongArrayValue( _
    ByVal elementName As String _
) As Long()

// C#
public long[] GetLongArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetLongValue method

Gets a long value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetLongValue( _
    ByVal childName As String _
) As Long

// C#
public long GetLongValue(
    string childName
);
```

### Parameters

◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetNullableBoolArrayValue method

Gets an array of bool values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetNullableBoolArrayValue( _
    ByVal elementName As String _
) As iAnywhere.QAnywhere.WS.NullableBool()

// C#
public iAnywhere.QAnywhere.WS.NullableBool[] GetNullableBoolArrayValue(
    string elementName
);
```

### Parameters

◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetNullableBoolValue method

Gets a bool value from this WSResult.

### Prototypes

#### ' Visual Basic

```
Public Function GetNullableBoolValue( _  
    ByVal childName As String _  
) As iAnywhere.QAnywhere.WS.NullableBool
```

#### // C#

```
public iAnywhere.QAnywhere.WS.NullableBool GetNullableBoolValue(  
    string childName  
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableDoubleArrayValue method

Gets an array of double values from this WSResult.

### Prototypes

#### ' Visual Basic

```
Public Function GetNullableDoubleArrayValue( _  
    ByVal elementName As String _  
) As iAnywhere.QAnywhere.WS.NullableDouble()
```

#### // C#

```
public iAnywhere.QAnywhere.WS.Nullabledouble[] GetNullableDoubleArrayValue(  
    string elementName  
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableDoubleValue method

Gets a double value from this WSResult.

### Prototypes

#### ' Visual Basic

```
Public Function GetNullableDoubleValue( _  
    ByVal childName As String _  
) As iAnywhere.QAnywhere.WS.NullableDouble
```

#### // C#

```
public iAnywhere.QAnywhere.WS.Nullabledouble GetNullableDoubleValue(  
    string childName  
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetNullableFloatArrayValue method

Gets an array of float values from this WSResult.

### Prototypes

#### ' Visual Basic

```
Public Function GetNullableFloatArrayValue( _  
    ByVal elementName As String _  
) As iAnywhere.QAnywhere.WS.NullableFloat()
```

#### // C#

```
public iAnywhere.QAnywhere.WS.NullableFloat[] GetNullableFloatArrayValue(  
    string elementName  
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetNullableFloatValue method

Gets a float value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetNullableFloatValue( _
    ByVal childName As String _
) As iAnywhere.QAnywhere.WS.NullableFloat

// C#
public iAnywhere.QAnywhere.WS.NullableFloat GetNullableFloatValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableIntArrayValue method

Gets an array of int values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetNullableIntArrayValue( _
    ByVal elementName As String _
) As iAnywhere.QAnywhere.WS.NullableInt()

// C#
public iAnywhere.QAnywhere.WS.NullableInt[] GetNullableIntArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableIntValue method

Gets an int value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetNullableIntValue( _
    ByVal childName As String _
) As iAnywhere.QAnywhere.WS.NullableInt

// C#
public iAnywhere.QAnywhere.WS.NullableInt GetNullableIntValue(
    string childName
);
```

### Parameters

◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableLongArrayValue method

Gets an array of long values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetNullableLongArrayValue( _
    ByVal elementName As String _
) As iAnywhere.QAnywhere.WS.NullableLong()

// C#
public iAnywhere.QAnywhere.WS.NullableLong[] GetNullableLongArrayValue(
    string elementName
);
```

### Parameters

◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableLongValue method

Gets an Int64 value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetNullableLongValue( _
    ByVal childName As String _
) As iAnywhere.QAnywhere.WS.NullableLong

// C#
public iAnywhere.QAnywhere.WS.NullableLong GetNullableLongValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableSByteArrayValue method

Gets an array of byte values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetNullableSByteArrayValue( _
    ByVal elementName As String _
) As iAnywhere.QAnywhere.WS.NullableSByte()

// C#
public iAnywhere.QAnywhere.WS.NullableSbyte[] GetNullableSByteArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableSByteValue method

Gets a byte value from this WSResult.

### Prototypes

#### ' Visual Basic

```
Public Function GetNullableSByteValue( _  
    ByVal childName As String _  
) As iAnywhere.QAnywhere.WS.NullableSByte
```

#### // C#

```
public iAnywhere.QAnywhere.WS.NullableSbyte GetNullableSByteValue(  
    string childName  
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableShortArrayValue method

Gets an array of short values from this WSResult.

### Prototypes

#### ' Visual Basic

```
Public Function GetNullableShortArrayValue( _  
    ByVal elementName As String _  
) As iAnywhere.QAnywhere.WS.NullableShort()
```

#### // C#

```
public iAnywhere.QAnywhere.WS.NullableShort[] GetNullableShortArrayValue(  
    string elementName  
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetNullableShortValue method

Gets a short value from this WSResult.

### Prototypes

#### ' Visual Basic

```
Public Function GetNullableShortValue( _  
    ByVal childName As String _  
) As iAnywhere.QAnywhere.WS.NullableShort
```

#### // C#

```
public iAnywhere.QAnywhere.WS.NullableShort GetNullableShortValue(  
    string childName  
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetObjectArrayValue method

Gets an array of Object values from this WSResult.

### Prototypes

#### ' Visual Basic

```
Public Function GetObjectArrayValue( _  
    ByVal elementName As String _  
) As Object()
```

#### // C#

```
public object[] GetObjectArrayValue(  
    string elementName  
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetObjectValue method

Gets an object value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetObjectValue( _
    ByVal childName As String _
) As Object

// C#
public object GetObjectValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetRequestID method

Gets the request ID that this WSResult represents.

### Prototypes

```
' Visual Basic
Public Function GetRequestID() As String

// C#
public string GetRequestID();
```

### Return value

The request ID.

### Remarks

This request ID should be persisted between runs of the application if it is desired to obtain a WSResult corresponding to a web service request in a run of the application different from when the request was made.

## GetSByteArrayValue method

Gets an array of sbyte values from this WSResult.

**Prototypes**

```
' Visual Basic
Public Function GetSByteArrayValue( _
    ByVal elementName As String _
) As System.SByte()

// C#
public System.Sbyte[] GetSByteArrayValue(
    string elementName
);
```

**Parameters**

- ◆ **elementName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetSByteValue method**

Gets an sbyte value from this WSResult.

**Prototypes**

```
' Visual Basic
Public Function GetSByteValue( _
    ByVal childName As String _
) As System.SByte

// C#
public System.Sbyte GetSByteValue(
    string childName
);
```

**Parameters**

- ◆ **childName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**GetSbyteValue method**

Gets an sbyte value from this WSResult.

## Prototypes

```
' Visual Basic
Public Function GetSbyteValue( _
    ByVal childName As String _
) As System.SByte

// C#
public System.Sbyte GetSbyteValue(
    string childName
);
```

## Parameters

- ◆ **childName** The element name in the WSDL document of this value.

## Return value

The value.

## Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetShortArrayValue method

Gets an array of short values from this WSResult.

## Prototypes

```
' Visual Basic
Public Function GetShortArrayValue( _
    ByVal elementName As String _
) As Short()

// C#
public short[] GetShortArrayValue(
    string elementName
);
```

## Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

## Return value

The value.

## Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetShortValue method

Gets a short value from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetShortValue( _
    ByVal childName As String _
) As Short

// C#
public short GetShortValue(
    string childName
);
```

### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetSingleArrayValue method

Gets an array of Single values from this WSResult.

### Prototypes

```
' Visual Basic
Public Function GetSingleArrayValue( _
    ByVal elementName As String _
) As Single()

// C#
public float [] GetSingleArrayValue(
    string elementName
);
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Return value

The value.

### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

## GetSingleValue method

Gets a Single value from this WSResult.

## Prototypes

```
' Visual Basic
Public Function GetSingleValue( _
    ByVal childName As String _
) As Single

// C#
public float GetSingleValue(
    string childName
);
```

## Parameters

- ◆ **childName** The element name in the WSDL document of this value.

## Return value

The value.

## Exceptions

- ◆ [WSException class](#) - Thrown if there is a problem getting the value.

## GetStatus method

Gets the status of this WSResult.

## Prototypes

```
' Visual Basic
Public Function GetStatus() As iAnywhere.QAnywhere.WS.WSStatus

// C#
public iAnywhere.QAnywhere.WS.WSStatus GetStatus();
```

## Return value

The status code.

## See also

- ◆ [“WSResult class” on page 355](#)
- ◆ [“WSResult members” on page 355](#)
- ◆ [“WSStatus enumeration” on page 388](#)

## GetStringArrayValue method

Gets an array of string values from this WSResult.

## Prototypes

```
' Visual Basic
Public Function GetStringArrayValue( _
    ByVal elementName As String _
) As String()
```

```
// C#
public string [] GetStringArrayValue(
    string elementName
);
```

#### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

#### Return value

The value.

#### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetStringValue method

Gets a string value from this WSResult.

#### Prototypes

```
' Visual Basic
Public Function GetStringValue( _
    ByVal childName As String _
) As String
```

```
// C#
public string GetStringValue(
    string childName
);
```

#### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

#### Return value

The value.

#### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetUIntArrayValue method

Gets an array of unsigned int values from this WSResult.

#### Prototypes

```
' Visual Basic
Public Function GetUIntArrayValue( _
    ByVal elementName As String _
) As UInt32()
```

```
// C#
public uint[] GetUIntArrayValue(
    string elementName
);
```

#### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

#### Return value

The value.

#### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetUIntValue method

Gets a unsigned int value from this WSResult.

#### Prototypes

```
' Visual Basic
Public Function GetUIntValue( _
    ByVal childName As String _
) As UInt32
```

```
// C#
public uint GetUIntValue(
    string childName
);
```

#### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

#### Return value

The value.

#### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetULongArrayValue method

Gets an array of unsigned long values from this WSResult.

#### Prototypes

```
' Visual Basic
Public Function GetULongArrayValue( _
    ByVal elementName As String _
) As UInt64()
```

```
// C#
public ulong[] GetULongArrayValue(
    string elementName
);
```

#### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

#### Return value

The value.

#### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetULongValue method

Gets a unsigned long value from this WSResult.

#### Prototypes

```
' Visual Basic
Public Function GetULongValue( _
    ByVal childName As String _
) As UInt64
```

```
// C#
public ulong GetULongValue(
    string childName
);
```

#### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

#### Return value

The value.

#### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetUShortArrayValue method

Gets an array of unsigned short values from this WSResult.

#### Prototypes

```
' Visual Basic
Public Function GetUShortArrayValue( _
    ByVal elementName As String _
) As UInt16()
```

```
// C#
public ushort[] GetUShortArrayValue(
    string elementName
);
```

#### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

#### Return value

The value.

#### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetUShortValue method

Gets a unsigned short value from this WSResult.

#### Prototypes

```
' Visual Basic
Public Function GetUShortValue( _
    ByVal childName As String _
) As UInt16
```

```
// C#
public ushort GetUShortValue(
    string childName
);
```

#### Parameters

- ◆ **childName** The element name in the WSDL document of this value.

#### Return value

The value.

#### Exceptions

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

### GetValue method

Gets the value of a complex type from this WSResult.

#### Prototypes

```
' Visual Basic
Public Function GetValue( _
    ByVal childName As String _
) As Object
```

```
// C#
public object GetValue(
    string childName
);
```

**Parameters**

- ◆ **childName** The element name in the WSDL document of this value.

**Return value**

The value.

**Exceptions**

- ◆ [WSEException class](#) - Thrown if there is a problem getting the value.

**SetLogger method**

Turns debug on or off.

**Prototypes**

```
' Visual Basic
Public Sub SetLogger( _
    ByVal wsLogger As iAnywhere.QAnywhere.WS.WSLogger _
)
```

```
// C#
public void SetLogger(
    iAnywhere.QAnywhere.WS.WSLogger wsLogger
);
```

**WSStatus enumeration**

This class defines codes for the status of a web service. request.

**Prototypes**

```
' Visual Basic
Public Enum WSStatus
```

```
// C#
public enum WSStatus
```

**Member name**

Member name	Description
STATUS_ERROR	There was an error processing the request.
STATUS_QUEUED	The request has been queued for delivery to the server.

<b>Member name</b>	<b>Description</b>
STATUS_RESULT_AVAILABLE	The result of the request is available.
STATUS_SUCCESS	The request was successful.

### About this chapter

This chapter describes the QAnywhere C++ API.

## AcknowledgementMode class

### Synopsis

```
public AcknowledgementMode
```

### Remarks

Indicates how messages should be acknowledged by QAnywhere client applications.

### See Also

[QAManager class](#)

[QATransactionalManager class](#)

[QAManagerBase class](#)

You can determine the mode of a [QAManagerBase class](#) instance using the `QAManagerBase::Mode` property.

For transactional messaging, use the [QATransactionalManager class](#). In this case, you use the [commit function](#) to acknowledge messages belonging to a transaction.

For more information, see [“Receiving messages synchronously” on page 75](#) and [“Receiving messages asynchronously” on page 76](#).

In implicit acknowledgement mode, messages are acknowledged as soon as they are received by a client application. In explicit acknowledgement mode, you must call one of the [QAManager class](#) acknowledgement methods. In transactional mode, you must call [commit function](#) to acknowledge all outstanding messages. The server propagates all status changes from client to client.

For more information, see [“Initializing a QAnywhere API” on page 54](#).

The `IMPLICIT_ACKNOWLEDGEMENT` and `EXPLICIT_ACKNOWLEDGEMENT` modes are assigned to a [QAManager class](#) instance using the [open function](#). The `TRANSACTIONAL` mode is implicitly assigned to [QATransactionalManager class](#) instances.

### Members

All members of `AcknowledgementMode`, including all inherited members.

- ◆ [“EXPLICIT\\_ACKNOWLEDGEMENT variable” on page 392](#)
- ◆ [“IMPLICIT\\_ACKNOWLEDGEMENT variable” on page 393](#)
- ◆ [“TRANSACTIONAL variable” on page 393](#)

## EXPLICIT\_ACKNOWLEDGEMENT variable

### Synopsis

```
const qa_short AcknowledgementMode::EXPLICIT_ACKNOWLEDGEMENT
```

**Remarks**

Indicates that received messages are acknowledged using one of the [QAManager class](#) acknowledge methods.

**IMPLICIT\_ACKNOWLEDGEMENT variable****Synopsis**

```
const qa_short AcknowledgementMode::IMPLICIT_ACKNOWLEDGEMENT
```

**Remarks**

Indicates that all messages are acknowledged as soon as they are received by a client application.

If you receive messages synchronously, messages are acknowledged as soon as the [getMessage function](#) returns. If you receive messages asynchronously, the message is acknowledged as soon as the event handling function returns.

**TRANSACTIONAL variable****Synopsis**

```
const qa_short AcknowledgementMode::TRANSACTIONAL
```

**Remarks**

Indicates that messages are only acknowledged as part of the ongoing transaction.

This mode is automatically assigned to [QATransactionalManager class](#) instances.

# MessageProperties class

## Synopsis

```
public MessageProperties
```

## Remarks

Provides fields storing standard message property names.

The MessageProperties class provides standard message property names. You can pass MessageProperties fields to [QAMessage class](#) methods used to get and set message properties.

For more information, see “[Message headers and message properties](#)” on page 206

```
QATextMessage * t_msg;
```

The following example gets the value corresponding to [MSG\\_TYPE variable](#) using the [getIntProperty function](#). The [MessageType class](#) enumeration maps the integer result to an appropriate message type.

```
int msg_type;
t_msg->getIntProperty( MessageProperties::MSG_TYPE, &msg_type)
```

The following example, evaluates the message type and RAS names using [MSG\\_TYPE variable](#) and [RASNAMES variable](#) respectively.

```
void SystemQueueListener::onMessage(QAMessage * msg) {
    QATextMessage *      t_msg;
    TCHAR                buffer[512];
    int                  len;
    int                  msg_type;

    t_msg = msg->castToTextMessage();
    if( t_msg != NULL ) {
        t_msg->getIntProperty( MessageProperties::MSG_TYPE, &msg_type );

        if( msg_type == MessageType::NETWORK_STATUS_NOTIFICATION ) {

            // get RAS names using MessageProperties::RASNAMES
            len = t_msg->getStringProperty(MessageProperties::RASNAMES,buffer,sizeof
(buffer));

        }

        //...
    }
}
```

## See Also

## Members

All members of MessageProperties, including all inherited members.

- ◆ “ADAPTER variable” on page 395
- ◆ “ADAPTERS variable” on page 395
- ◆ “DELIVERY\_COUNT variable” on page 396
- ◆ “IP variable” on page 396
- ◆ “MAC variable” on page 397
- ◆ “MSG\_TYPE variable” on page 397
- ◆ “NETWORK\_STATUS variable” on page 397
- ◆ “ORIGINATOR variable” on page 398
- ◆ “RAS variable” on page 398
- ◆ “RASNAMES variable” on page 399
- ◆ “STATUS variable” on page 399
- ◆ “STATUS\_TIME variable” on page 399
- ◆ “TRANSMISSION\_STATUS variable” on page 400

## ADAPTER variable

### Synopsis

```
const qa_string MessageProperties::ADAPTER
```

### Remarks

This property name refers to the currently active network adapter that is being used to connect to the QAnywhere server.

It is used for system queue messages.

The value of this field is "ias\_Network.Adapter".

Pass [ADAPTER variable](#) as the first parameter to [getStringProperty function](#) to access the associated message property.

For more information, see [“Message properties” on page 209](#).

### See Also

MessageProperties

## ADAPTERS variable

### Synopsis

```
const qa_string MessageProperties::ADAPTERS
```

### Remarks

This property name refers to a delimited list of network adapters that can be used to connect to the QAnywhere server.

It is used for system queue messages.

The value of this field is "ias\_Adapters".

Pass [ADAPTERS variable](#) as the first parameter to [getStringProperty function](#) to access the associated message property.

For more information, see [“Message properties” on page 209](#).

#### See Also

MessageProperties

## DELIVERY\_COUNT variable

#### Synopsis

```
const qa_string MessageProperties::DELIVERY_COUNT
```

#### Remarks

This property name refers to the number of attempts that have been made so far to deliver the message.

The value of this field is "ias\_DeliveryCount".

Pass [DELIVERY\\_COUNT variable](#) as the first parameter in [setStringProperty function](#) or [getStringProperty function](#) to access the associated message property.

#### See Also

MessageProperties

## IP variable

#### Synopsis

```
const qa_string MessageProperties::IP
```

#### Remarks

This property name refers to the IP address of the currently active network adapter that is being used to connect to the QAnywhere server.

It is used for system queue messages.

The value of this field is "ias\_Network.IP".

Pass [IP variable](#) as the first parameter to [getStringProperty function](#) to access the associated message property.

For more information, see [“Message properties” on page 209](#).

#### See Also

MessageProperties

## MAC variable

### Synopsis

```
const qa_string MessageProperties::MAC
```

### Remarks

This property name refers to the MAC address of the currently active network adapter that is being used to connect to the QAnywhere server.

It is used for system queue messages.

The value of this field is "ias\_Network.MAC".

Pass [MAC variable](#) as the first parameter to [getStringProperty function](#) to access the associated message property.

For more information, see [“Message properties” on page 209](#).

### See Also

[MessageProperties](#)

## MSG\_TYPE variable

### Synopsis

```
const qa_string MessageProperties::MSG_TYPE
```

### Remarks

This property name refers to [MessageType class](#) enumeration values associated with a QAnywhere message.

The value of this field is "ias\_MessageType". Pass [MSG\\_TYPE variable](#) as the first parameter in [setIntProperty function](#) or [getIntProperty function](#) to determine the associated property.

### See Also

[MessageType class](#)

[MessageProperties](#)

## NETWORK\_STATUS variable

### Synopsis

```
const qa_string MessageProperties::NETWORK_STATUS
```

### Remarks

This property name refers to the state of the network connection.

The value of this field is "ias\_NetworkStatus".

The value of this property is 1 if the network is accessible and 0 otherwise. The network status is used for system queue messages (for example, network status changes).

For more information, see [“Message properties” on page 209](#).

Pass [NETWORK\\_STATUS variable](#) as the first parameter in [setStringProperty function](#) or [getStringProperty function](#) to access the associated message property.

#### See Also

MessageProperties

## ORIGINATOR variable

#### Synopsis

```
const qa_string MessageProperties::ORIGINATOR
```

#### Remarks

This property name refers to the message store ID of the originator of the message.

The value of this field is "ias\_Originator".

Pass [ORIGINATOR variable](#) as the first parameter in [setStringProperty function](#) or [getStringProperty function](#) to access the associated message property.

#### See Also

MessageProperties

## RAS variable

#### Synopsis

```
const qa_string MessageProperties::RAS
```

#### Remarks

This property name refers to the currently active RAS name that is being used to connect to the QAnywhere server.

It is used for system queue messages.

The value of this field is "ias\_Network.RAS".

Pass [RAS variable](#) as the first parameter to [getStringProperty function](#) to access the associated message property.

For more information, see [“Message properties” on page 209](#).

#### See Also

MessageProperties

## RASNAMES variable

### Synopsis

```
const qa_string MessageProperties::RASNAMES
```

### Remarks

This property name refers to a delimited list of RAS entry names that can be used to connect to the QAnywhere server.

It is used for system queue messages.

The value of this field is "ias\_RASNames".

For more information, see [“Message properties” on page 209](#).

Pass [RASNAMES variable](#) as the first parameter in [setStringProperty function](#) or [getStringProperty function](#) to access the associated message property.

### See Also

[MessageProperties](#)

## STATUS variable

### Synopsis

```
const qa_string MessageProperties::STATUS
```

### Remarks

This property name refers to the current status of the message.

For a list of values, see the [StatusCodes class](#) enumeration. The value of this field is "ias\_Status".

Pass [STATUS variable](#) as the first parameter in [setIntProperty function](#) or [getIntProperty function](#) to access the associated message property.

### See Also

[StatusCodes class](#)

[MessageProperties](#)

## STATUS\_TIME variable

### Synopsis

```
const qa_string MessageProperties::STATUS_TIME
```

### Remarks

This property name refers to the time at which the message received its current status.

It is in units that are natural for the platform. For Windows/PocketPC platforms, the timestamp is the SYSTEMTIME, converted to a FILETIME, which is copied to a qa\_long value. It is a local time. The value of this field is "ias\_StatusTime".

Pass [STATUS\\_TIME variable](#) as the first parameter in [getLongProperty function](#) to access the associated read-only message property.

**See Also**

[MessageProperties](#)

## **TRANSMISSION\_STATUS variable**

**Synopsis**

```
const qa_string MessageProperties::TRANSMISSION_STATUS
```

**Remarks**

This property name refers to the current transmission status of the message.

For a list of values, see the [StatusCodes class](#) enumeration. The value of this field is "ias\_TransmissionStatus".

Pass [TRANSMISSION\\_STATUS variable](#) as the first parameter in [setIntProperty function](#) or [getIntProperty function](#) to access the associated message property.

**See Also**

[StatusCodes class](#)

[MessageProperties](#)

## MessageStoreProperties class

### Synopsis

```
public MessageStoreProperties
```

### Remarks

The MessageStoreProperties class provides standard message property names.

You can pass [MessageProperties class](#) fields to [QAManagerBase class](#) methods used to get and set pre-defined or custom message store properties. For more information, see “[Client message store properties](#)” on page 215.

### Members

All members of MessageStoreProperties, including all inherited members.

- ◆ [“MAX\\_DELIVERY\\_ATTEMPTS variable” on page 401](#)

## MAX\_DELIVERY\_ATTEMPTS variable

### Synopsis

```
const qa_string MessageStoreProperties::MAX_DELIVERY_ATTEMPTS
```

### Remarks

This property name refers to the maximum number of times that a message can be received, without explicit acknowledgement, before its status is set to [UNRECEIVABLE variable](#).

The value of this field is "ias\_MaxDeliveryAttempts".

### See Also

[StatusCodes class](#).

MessageStoreProperties

## MessageType class

### Synopsis

```
public MessageType
```

### Remarks

Defines constant values for the [MSG\\_TYPE](#) variable message property.

The following example shows the `onSystemMessage` method which is used to handle QAnywhere system messages. The message type is compared to [NETWORK\\_STATUS\\_NOTIFICATION](#) variable.

```
void SystemQueueListener::onMessage(QAMessage * msg)
{
    QATextMessage *      t_msg;
    TCHAR                buffer[512];
    int                  len;
    int                  msg_type;

    t_msg = msg->castToTextMessage();
    if( t_msg != NULL ) {
        t_msg->getIntProperty( MessageProperties::MSG_TYPE, &msg_type );
        if( msg_type == MessageType::NETWORK_STATUS_NOTIFICATION ) {

            // get network names using MessageProperties::NETWORK
            len = t_msg->getStringProperty(MessageProperties::NETWORK,buffer,sizeof
(buffer));

        }

        //...
    }
}
```

### Members

All members of `MessageType`, including all inherited members.

- ◆ [“NETWORK\\_STATUS\\_NOTIFICATION](#) variable” on page 402
- ◆ [“PUSH\\_NOTIFICATION](#) variable” on page 403
- ◆ [“REGULAR](#) variable” on page 403

## NETWORK\_STATUS\_NOTIFICATION variable

### Synopsis

```
const qa_int MessageType::NETWORK_STATUS_NOTIFICATION
```

### Remarks

Identifies a QAnywhere system message used to notify QAnywhere client applications of network status changes.

Network status changes apply to the device receiving the system message. Use [ADAPTER variable](#), `MessageProperties::NETWORK`, and [NETWORK\\_STATUS variable](#) fields to identify new network status information.

For more information, see [“Pre-defined message properties” on page 209](#).

## **PUSH\_NOTIFICATION variable**

### **Synopsis**

```
const qa_int MessageType::PUSH_NOTIFICATION
```

### **Remarks**

Identifies a QAnywhere system message used to notify QAnywhere client applications of push notifications.

If you use the on-demand qaagent policy, a typical response is to call [triggerSendReceive function](#) to receive messages waiting with the central message server.

For more information, see [“Pre-defined message properties” on page 209](#).

## **REGULAR variable**

### **Synopsis**

```
const qa_int MessageType::REGULAR
```

### **Remarks**

If no message type property exists then the message type is assumed to be REGULAR.

This type of message is not treated specially by the message system.

## QABinaryMessage class

### Synopsis

```
public QABinaryMessage
```

### Base classes

- ◆ [“QAMessage class” on page 466](#)

### Remarks

A QABinaryMessage object is used to send a message containing a stream of uninterpreted bytes.

It inherits from the [QAMessage class](#) and adds a bytes message body. QABinaryMessage provides a variety of functions to read from and write to the bytes message body.

When the message is first created, the body of the message is write-only. After a message has been sent, the client that sent it can retain and modify it without affecting the message that has been sent. The same message object can be sent multiple times.

When a message is received, the provider has called [reset function](#) so that the message body is in read-only mode and reading of values starts from the beginning of the message body. If a client attempts to write a message in read-only mode, a COMMON\_MSG\_NOT\_WRITEABLE\_ERROR is set.

The following example uses the QABinaryMessage writeString function to write the string "Q" followed by the string "Anywhere" to a QABinaryMessage instances message body.

```
// create a binary message instance
QABinaryMessage * binary_message;
binary_message = qa_manager->createBinaryMessage();

// set optional message properties ...
binary_message->setReplyToAddress( "my-queue-name" );

// write to the message body
binary_message->writeString("Q");
binary_message->writeString("Anywhere");

// put the message in the local database, ready for sending

if( !qa_manager->putMessage( "store-id\\queue-name", msg ) ) {
    handleError();
}
```

Note: on the receiving end, the first [readString function](#) invocation returns "Q" and the next [readString function](#) invocation returns "Anywhere".

The message is sent by the QAnywhere Agent. For more information, see [“Determining when message transmission should occur on the client” on page 36](#) and [“Writing QAnywhere Client Applications” on page 45](#).

## getBodyLength function

### Synopsis

```
virtual qa_long QABinaryMessage::getBodyLength()
```

### Remarks

Returns the size of the message body in bytes.

### See Also

QABinaryMessage

## readBinary function

### Synopsis

```
virtual qa_int QABinaryMessage::readBinary(  
    qa_bytes value,  
    qa_int length  
)
```

### Parameters

- ◆ **value** The buffer into which the data is read.
- ◆ **length** The maximum number of bytes to read.

**Remarks**

Reads a specified number of bytes starting from the unread portion of the QABinaryMessage instance's message body.

**See Also**

QABinaryMessage

[writeBinary function](#)

**Returns**

The total number of bytes read into the buffer, or -1 if there is no more data because the end of the stream has been reached.

## readBoolean function

**Synopsis**

```
virtual qa_bool QABinaryMessage::readBoolean(  
    qa_bool * value  
)
```

**Parameters**

◆ **value** The destination of the qa\_bool value read from the bytes message stream.

**Remarks**

Reads a boolean value starting from the unread portion of the QABinaryMessage instance's message body.

**See Also**

QABinaryMessage

[writeBoolean function](#)

**Returns**

True if and only if the operation succeeded.

## readByte function

**Synopsis**

```
virtual qa_bool QABinaryMessage::readByte(  
    qa_byte * value  
)
```

**Parameters**

◆ **value** The destination of the qa\_byte value read from the bytes message stream.

### Remarks

Reads a signed 8-bit value starting from the unread portion of the `QABinaryMessage` instance's message body.

### See Also

`QABinaryMessage`

[writeByte function](#)

### Returns

True if and only if the operation succeeded.

## readChar function

### Synopsis

```
virtual qa_bool QABinaryMessage::readChar(  
    qa_char * value  
)
```

### Parameters

◆ **value** The destination of the `qa_char` value read from the bytes message stream.

### Remarks

Reads a character value starting from the unread portion of the `QABinaryMessage` instance's message body.

### See Also

`QABinaryMessage`

[writeChar function](#)

### Returns

The character value read.

## readDouble function

### Synopsis

```
virtual qa_bool QABinaryMessage::readDouble(  
    qa_double * value  
)
```

### Parameters

◆ **value** The destination of the double value read from the bytes message stream.

**Remarks**

Reads a double value starting from the unread portion of the QABinaryMessage instance's message body.

**See Also**

QABinaryMessage

[writeDouble function](#)

**Returns**

True if and only if the operation succeeded.

## readFloat function

**Synopsis**

```
virtual qa_bool QABinaryMessage::readFloat(  
    qa_float * value  
)
```

**Parameters**

◆ **value** The destination of the float value read from the bytes message stream.

**Remarks**

Reads a float value starting from the unread portion of the QABinaryMessage instance's message body.

**See Also**

QABinaryMessage

[writeFloat function](#)

**Returns**

True if and only if the operation succeeded.

## readInt function

**Synopsis**

```
virtual qa_bool QABinaryMessage::readInt(  
    qa_int * value  
)
```

**Parameters**

◆ **value** The destination of the qa\_int value read from the bytes message stream.

### Remarks

Reads a signed 32-bit integer value starting from the unread portion of the `QABinaryMessage` instance's message body.

### See Also

`QABinaryMessage`

[writeInt function](#)

### Returns

True if and only if the operation succeeded.

## readLong function

### Synopsis

```
virtual qa_bool QABinaryMessage::readLong(  
    qa_long * value  
)
```

### Parameters

◆ **value** The destination of the long value read from the bytes message stream.

### Remarks

Reads a signed 64-bit integer value starting from the unread portion of the `QABinaryMessage` instance's message body.

### See Also

`QABinaryMessage`

[writeLong function](#)

### Returns

True if and only if the operation succeeded.

## readShort function

### Synopsis

```
virtual qa_bool QABinaryMessage::readShort(  
    qa_short * value  
)
```

### Parameters

◆ **value** The destination of the `qa_short` value read from the bytes message stream.

**Remarks**

Reads a signed 16-bit value starting from the unread portion of the QABinaryMessage instance's message body.

**See Also**

QABinaryMessage

[writeShort function](#)

**Returns**

True if and only if the operation succeeded.

## readString function

**Synopsis**

```
virtual qa_int QABinaryMessage::readString(  
    qa_string dest,  
    qa_int maxLen  
)
```

**Parameters**

- ◆ **dest** The destination of the `qa_string` value read from the bytes message stream.
- ◆ **maxLen** The maximum number of characters to read, including the null terminator character.

**Remarks**

Reads a string value starting from the unread portion of the QABinaryMessage instance's message body.

**See Also**

QABinaryMessage

[writeString function](#)

**Returns**

The total number of non-null `qa_chars` read into the buffer, -1 if there is no more data or an error occurred, or -2 if the buffer is too small.

## reset function

**Synopsis**

```
virtual void QABinaryMessage::reset()
```

**Remarks**

Resets a message so that the reading of values starts from the beginning of the message body.

The Reset method also puts the QABinaryMessage message body in read-only mode.

### See Also

QABinaryMessage

## writeBinary function

### Synopsis

```
virtual void QABinaryMessage::writeBinary(  
    qa_const_bytes value,  
    qa_int offset,  
    qa_int length  
)
```

### Parameters

- ◆ **value** The byte array value to write to the message body.
- ◆ **offset** The offset within the byte array to begin writing.
- ◆ **length** The number of bytes to write.

### Remarks

Appends a byte array value to the QABinaryMessage instance's message body.

### See Also

QABinaryMessage

[readBinary function](#)

## writeBoolean function

### Synopsis

```
virtual void QABinaryMessage::writeBoolean(  
    qa_bool value  
)
```

### Parameters

- ◆ **value** The boolean value to write to the message body.

### Remarks

Appends a boolean value to the QABinaryMessage instance's message body.

The boolean is represented as a one-byte value. True is represented as 1; false is represented as 0.

**See Also**

QABinaryMessage  
[readBoolean function](#)

**writeByte function****Synopsis**

```
virtual void QABinaryMessage::writeByte(  
    qa_byte value  
)
```

**Parameters**

◆ **value** The byte array value to write to the message body.

**Remarks**

Appends a byte value to the QABinaryMessage instance's message body.

The byte is represented as a one-byte value.

**See Also**

QABinaryMessage  
[readByte function](#)

**writeChar function****Synopsis**

```
virtual void QABinaryMessage::writeChar(  
    qa_char value  
)
```

**Parameters**

◆ **value** the char value to write to the message body.

**Remarks**

Appends a char value to the QABinaryMessage instance's message body.

The char parameter is represented as a two-byte value and the high order byte is appended first.

**See Also**

QABinaryMessage  
[readChar function](#)

## writeDouble function

### Synopsis

```
virtual void QABinaryMessage::writeDouble(  
    qa_double value  
)
```

### Parameters

- ◆ **value** The double value to write to the message body.

### Remarks

Appends a double value to the QABinaryMessage instance's message body.

The double parameter is converted to a representative eight-byte long value. Higher order bytes are appended first.

### See Also

QABinaryMessage

[readDouble function](#)

## writeFloat function

### Synopsis

```
virtual void QABinaryMessage::writeFloat(  
    qa_float value  
)
```

### Parameters

- ◆ **value** The float value to write to the message body.

### Remarks

Appends a float value to the QABinaryMessage instance's message body.

The float parameter is converted to a representative 4-byte integer and the higher order bytes are appended first.

### See Also

QABinaryMessage

[readFloat function](#)

## writeInt function

### Synopsis

```
virtual void QABinaryMessage::writeInt(  
    qa_int value  
)
```

### Parameters

◆ **value** the int value to write to the message body.

### Remarks

Appends an integer value to the QABinaryMessage instance's message body.

The integer parameter is represented as a four-byte value and higher order bytes are appended first.

### See Also

QABinaryMessage

[readInt function](#)

## writeLong function

### Synopsis

```
virtual void QABinaryMessage::writeLong(  
    qa_long value  
)
```

### Parameters

◆ **value** The long value to write to the message body.

### Remarks

Appends a long value to the QABinaryMessage instance's message body.

The long parameter is represented as an eight-byte value and higher order bytes are appended first.

### See Also

QABinaryMessage

[readLong function](#)

## writeShort function

### Synopsis

```
virtual void QABinaryMessage::writeShort(  
    qa_short value  
)
```

### Parameters

- ◆ **value** The short value to write to the message body.

### Remarks

Appends a short value to the QABinaryMessage instance's message body.

The short parameter is represented as a two-byte value and the higher order byte is appended first.

### See Also

QABinaryMessage

[readShort function](#)

## writeString function

### Synopsis

```
virtual void QABinaryMessage::writeString(  
    qa_const_string value  
)
```

### Parameters

- ◆ **value** The string value to write to the message body.

### Remarks

Appends a string value to the QABinaryMessage instance's message body.

*Note:* The receiving application needs to invoke [readString function](#) for each writeString invocation.

*Note:* The UTF-8 representation of the string can be at most 32767 bytes.

### See Also

QABinaryMessage

[readString function](#)

## **~QABinaryMessage function**

### **Synopsis**

virtual **QABinaryMessage::~~QABinaryMessage()**

### **Remarks**

Virtual destructor.

## QAEError class

### Synopsis

```
public QAEError
```

### Remarks

This class defines error constants associated with a QAnywhere client application.

A QAEError object is used internally by the [QAManager class](#) object to keep track of errors associated with messaging operations. The application programmer should not need to create an instance of this class. The error constants should be used by the application programmer to interpret error codes returned by [getLastError function](#)

### See Also

[getLastErrorMsg function](#)

```
if (qa_mgr->getLastError() != QAEError::QA_NO_ERROR)
{
    //process error
}
```

# QAManager class

## Synopsis

public **QAManager**

## Base classes

- ◆ [“QAManagerBase class” on page 432](#)

## Remarks

The QAManager class derives from [QAManagerBase class](#) and manages non-transactional QAnywhere messaging operations.

For a detailed description of derived behavior, see [QAManagerBase class](#).

The QAManager can be configured for implicit or explicit acknowledgement as defined in the [AcknowledgementMode class](#) enumeration. To acknowledge messages as part of a transaction, use [QATransactionalManager class](#).

Use the [QAManagerFactory class](#) to create QAManager and [QATransactionalManager class](#) objects.

## Members

All members of QAManager, including all inherited members.

## acknowledge function

### Synopsis

```
virtual qa_bool QAManager::acknowledge(  
    QAMessage * msg  
)
```

### Parameters

- ◆ **msg** The message to acknowledge.

### Remarks

Acknowledges that the client application successfully received a QAnywhere message.

*Note:* when a [QAMessage class](#) is acknowledged, its [STATUS variable](#) property changes to [RECEIVED variable](#). When a [QAMessage class](#) status changes to [RECEIVED variable](#), it can be deleted using the default delete rule.

For more information about delete rules, see [“Message delete rules” on page 239](#).

### See Also

[QAManager](#)

[acknowledgeAll function](#)

[acknowledgeUntil function](#)

### Returns

True if and only if the operation succeeded.

## acknowledgeAll function

### Synopsis

```
virtual qa_bool QAManager::acknowledgeAll()
```

### Remarks

Acknowledges that the client application successfully received all unacknowledged QAnywhere messages.

*Note:* when a [QAMessage class](#) is acknowledged, its [STATUS variable](#) property changes to [RECEIVED variable](#). When a [QAMessage class](#) status changes to [RECEIVED variable](#), it can be deleted using the default delete rule.

For more information about delete rules, see [“Message delete rules” on page 239](#).

### See Also

[QAManager](#)

[acknowledge function](#)

[acknowledgeUntil function](#)

### Returns

True if and only if the operation succeeded.

## acknowledgeUntil function

### Synopsis

```
virtual qa_bool QAManager::acknowledgeUntil(  
    QAMessage * msg  
)
```

**Parameters**

- ◆ **msg** The last message to acknowledge. All earlier unacknowledged messages are also acknowledged.

**Remarks**

Acknowledges the given [QAMessage class](#) instance and all unacknowledged messages received before the given message.

*Note:* when a [QAMessage class](#) is acknowledged, its [STATUS variable](#) property changes to [RECEIVED variable](#). When a [QAMessage class](#) status changes to [RECEIVED variable](#), it can be deleted using the default delete rule.

For more information about delete rules, see “[Message delete rules](#)” on page 239.

**See Also**

[QAManager](#)

[acknowledge function](#)

[acknowledgeAll function](#)

**Returns**

True if and only if the operation succeeded.

**open function****Synopsis**

```
virtual qa_bool QAManager::open(  
    qa_short mode  
)
```

**Parameters**

- ◆ **mode** The acknowledgement mode.

**Remarks**

Opens the QAManager with the given [AcknowledgementMode class](#) value.

The [open function](#) must be the first method called after creating a QAManager.

**See Also**

[QAManager](#)

[AcknowledgementMode class](#)

**Returns**

True if and only if the operation succeeded.

## recover function

### Synopsis

virtual qa\_bool **QAManager::recover()**

### Remarks

Force all unacknowledged messages into a state of unreceived.

That is, these messages must be received again using [getMessage function](#).

### Returns

True if and only if the operation succeeded.

## QAManagerBase class

### Synopsis

```
public QAManagerBase
```

### Derived classes

- ◆ [“QAManager class” on page 427](#)
- ◆ [“QATransactionalManager class” on page 492](#)

### Remarks

This class acts as a base class for [QATransactionalManager class](#) and [QAManager class](#), which manage transactional and non-transactional messaging, respectively.

Use the [start function](#) to allow a QAManagerBase instance to listen for messages. There must be only a single instance of QAManagerBase per thread in your application. For more information about qaagent transmission policies, see [“Determining when message transmission should occur on the client” on page 36](#).

You can use instances of this class to create and manage QAnywhere messages. Use the [createBinaryMessage function](#) and the [createTextMessage function](#) to create appropriate [QAMessage class](#) instances. [QAMessage class](#) instances provide a variety of methods to set message content and properties. To send QAnywhere messages, use the [putMessage function](#) to place the addressed message in the local message store queue. The message is transmitted by the QAnywhere Agent based on its transmission policies or when you call the [triggerSendReceive function](#).

Messages are released from memory when you close a QAManagerBase instance using the [close function](#). For more information, see [“Client message store properties” on page 215](#) and the [MessageStoreProperties class](#).

You can use [getLastError function](#) and `QAManagerBase::getLastErrorMessage` to return error information when a QAException occurs. QAManagerBase also provides methods to set and get message store properties.

## beginEnumStorePropertyNames function

### Synopsis

virtual qa\_store\_property\_enum\_handle **QAManagerBase::beginEnumStorePropertyNames()**

### Remarks

Begins an enumeration of message store property names.

The handle returned by this method is supplied to the [nextStorePropertyName function](#). This method and the [nextStorePropertyName function](#) can be used to enumerate the message store property names at the time this method was called. Message store properties cannot be set between the [beginEnumStorePropertyNames](#) and the [endEnumStorePropertyNames function](#) calls.

### See Also

[QAManagerBase](#)

### Returns

A handle that is supplied to [nextStorePropertyName function](#).

## browseClose function

### Synopsis

```
virtual void QAManagerBase::browseClose(  
    qa_browse_handle handle  
)
```

### Parameters

◆ **handle** A handle returned by one of the begin browse operations.

### Remarks

Frees the resources associated with a browse operation.

### See Also

[QAManagerBase](#)

## browseMessages function

### Synopsis

```
virtual qa_browse_handle QAManagerBase::browseMessages()
```

### Remarks

Begins a browse of messages queued in the message store.

The handle returned by this method is supplied to [browseNextMessage function](#). This method and the [browseNextMessage function](#) can be used to enumerate the messages in the message store at the time this method was called.

The messages are just being browsed, so they cannot be acknowledged. Use [getMessage function](#) to receive messages so they can be acknowledged.

### See Also

[browseNextMessage function](#)

[browseMessagesByQueue function](#)

[browseMessagesByID function](#)

[browseClose function](#)

QAManagerBase

### Returns

A handle that is supplied to [browseNextMessage function](#)

## **browseMessagesByID function**

### Synopsis

```
virtual qa_browse_handle QAManagerBase::browseMessagesByID(  
    qa_const_string msgid  
)
```

### Parameters

◆ **msgid** The message ID.

### Remarks

Begins a browse of the message that is queued in the message store, with the given message ID.

The handle returned by this method is supplied to [browseNextMessage function](#). This method and [browseNextMessage function](#) can be used to enumerate the messages in the message store at the time this method was called.

The messages are just being browsed, so they cannot be acknowledged. Use [getMessage function](#) to receive messages so they can be acknowledged.

### See Also

[browseNextMessage function](#)

[browseMessagesByQueue function](#)

QAManagerBase::BrowseMessages()

[browseClose function](#)

QAManagerBase

### Returns

A handle that is supplied to [browseNextMessage](#).

## browseMessagesByQueue function

### Synopsis

```
virtual qa_browse_handle QAManagerBase::browseMessagesByQueue(  
    qa_const_string address  
)
```

### Parameters

◆ **address** The queue in which to browse.

### Remarks

Begins a browse of messages queued in the message store for the given queue.

The handle returned by this method is supplied to [browseNextMessage function](#). This method and [browseNextMessage function](#) can be used to enumerate the messages in the message store at the time this method was called.

The messages are just being browsed, so they cannot be acknowledged. Use [getMessage function](#) to receive messages so they can be acknowledged.

### See Also

[browseNextMessage function](#)

[browseMessagesByID function](#)

`QAManagerBase::BrowseMessages()`

[browseClose function](#)

`QAManagerBase`

### Returns

A handle that is supplied to [browseNextMessage](#).

## browseMessagesBySelector function

### Synopsis

```
virtual qa_browse_handle QAManagerBase::browseMessagesBySelector(  
    qa_const_string selector  
)
```

### Parameters

◆ **selector** The selector.

### Remarks

Begins a browse of messages queued in the message store that satisfy the given selector.

The handle returned by this method is supplied to [browseNextMessage function](#). This method and [browseNextMessage function](#) can be used to enumerate the messages in the message store at the time this method was called.

The messages are just being browsed, so they cannot be acknowledged.

Use [getMessage function](#) to receive messages so they can be acknowledged.

### See Also

[browseNextMessage function](#)

[browseMessagesByID function](#)

[browseMessagesByQueue function](#)

[QAManagerBase::BrowseMessages\(\)](#)

[browseClose function](#)

[QAManagerBase](#)

### Returns

A handle that is supplied to [browseNextMessage](#).

## **browseNextMessage function**

### Synopsis

```
virtual QAMessage * QAManagerBase::browseNextMessage(  
    qa_browse_handle handle  
)
```

### Parameters

◆ **handle** A handle returned by one of the begin browse operations.

### Remarks

Returns the next message for the given browse operation, returning null if there are no more messages.

To obtain the handle to browsed messages, use [browseMessages function](#) or other [QAManagerBase](#) methods which allow you to browse messages by queue or message ID.

### See Also

[QAManagerBase::BrowseMessages\(\)](#)

[browseMessagesByQueue function](#)

[browseMessagesByID function](#)

[browseClose function](#)

[QAManagerBase](#)

**Returns**

The next message, or `qa_null` if there are no more messages.

**cancelMessage function****Synopsis**

```
virtual qa_bool QAManagerBase::cancelMessage(  
    qa_const_string msgid  
)
```

**Parameters**

- ◆ **msgid** The ID of the message to cancel.

**Remarks**

Cancels the message with the given message ID.

`cancelMessage` puts a message into a cancelled state before it is transmitted. With the default delete rules of the QAnywhere Agent, cancelled messages are eventually deleted from the message store. `cancelMessage` fails if the message is already in a final state, or if it has been transmitted to the central messaging server.

For more information about delete rules, see [“Message delete rules” on page 239](#).

**See Also**

`QAManagerBase`

**Returns**

True if and only if the operation succeeded.

**close function****Synopsis**

```
virtual qa_bool QAManagerBase::close()
```

**Remarks**

Closes the connection to the QAnywhere message system and releases any resources used by the `QAManagerBase`.

Subsequent calls to [close function](#) are ignored. When an instance of `QAManagerBase` is closed, it cannot be re-opened; you must create and open a new `QAManagerBase` instance in this case.

**See Also**

[open function](#)

[open function](#)

`QAManagerBase`

**Returns**

True if and only if the operation succeeded.

**createBinaryMessage function****Synopsis**

```
virtual QABinaryMessage * QAManagerBase::createBinaryMessage()
```

**Remarks**

Creates a [QABinaryMessage class](#) instance.

A [QABinaryMessage class](#) instance is used to send a message containing a message body of uninterpreted bytes.

**See Also**

[QABinaryMessage class](#)

QAManagerBase

**Returns**

A new [QABinaryMessage class](#) instance.

**createTextMessage function****Synopsis**

```
virtual QATextMessage * QAManagerBase::createTextMessage()
```

**Remarks**

Creates a [QATextMessage class](#) instance.

A [QATextMessage class](#) object is used to send a message containing a string message body.

**See Also**

[QATextMessage class](#)

QAManagerBase

**Returns**

A new [QATextMessage class](#) instance.

## deleteMessage function

### Synopsis

```
virtual void QAManagerBase::deleteMessage(  
    QAMessage * msg  
)
```

### Parameters

◆ **msg** The message to delete.

### Remarks

Deletes a [QAMessage class](#) object.

By default, messages created by `QAManagerBase::createTextMessage` or [createBinaryMessage function](#) are deleted automatically when the `QAManagerBase` is closed. This method allows more control over when messages are deleted.

### See Also

`QAManagerBase`

## endEnumStorePropertyNames function

### Synopsis

```
virtual void QAManagerBase::endEnumStorePropertyNames(  
    qa_store_property_enum_handle h  
)
```

### Parameters

◆ **h** A handle returned by `beginEnumStorePropertyNames`.

### Remarks

Frees the resources associated with a message store property name enumeration.

### See Also

`QAManagerBase`

## getAllQueueDepth function

### Synopsis

```
virtual qa_int QAManagerBase::getAllQueueDepth(  
    qa_short filter  
)
```

**Parameters**

- ◆ **filter** A filter indicating incoming messages, outgoing messages, or all messages.

**Remarks**

Returns the total depth of all queues, based on a given filter.

The depth of a queue is the number of messages which have not been received (for example, using [getMessage function](#)).

**See Also**

[QAManagerBase](#)

**Returns**

The number of messages, or -1 if an error occurs.

**See Also**

[QueueDepthFilter class](#).

## **getBooleanStoreProperty function**

**Synopsis**

```
virtual qa_bool QAManagerBase::getBooleanStoreProperty(  
    qa_const_string name,  
    qa_bool * value  
)
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The destination for the boolean value.

**Remarks**

Gets a boolean value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

**See Also**

[QAManagerBase](#)

**Returns**

True if and only if the operation succeeded.

## getBytesStoreProperty function

### Synopsis

```
virtual qa_bool QAManagerBase::getBytesStoreProperty(  
    qa_const_string name,  
    qa_byte * value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The destination for the byte value.

### Remarks

Gets a byte value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

### See Also

QAManagerBase

### Returns

True if and only if the operation succeeded.

## getDoubleStoreProperty function

### Synopsis

```
virtual qa_bool QAManagerBase::getDoubleStoreProperty(  
    qa_const_string name,  
    qa_double * value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The destination for the double value.

### Remarks

Gets a double value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

**See Also**

QAManagerBase

**Returns**

True if and only if the operation succeeded.

## getFloatStoreProperty function

**Synopsis**

```
virtual qa_bool QAManagerBase::getFloatStoreProperty(  
    qa_const_string name,  
    qa_float * value  
)
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The destination for the float value.

**Remarks**

Gets a float value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

**See Also**

QAManagerBase

**Returns**

True if and only if the operation succeeded.

## getIntStoreProperty function

**Synopsis**

```
virtual qa_bool QAManagerBase::getIntStoreProperty(  
    qa_const_string name,  
    qa_int * value  
)
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The destination for the int value.

### Remarks

Gets an int value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

### See Also

[QAManagerBase](#)

### Returns

True if and only if the operation succeeded.

## getLastError function

### Synopsis

```
virtual qa_int QAManagerBase::getLastError()
```

### Remarks

The error code associated with the last executed QAManagerBase method.

0 indicates no error.

For a list of values, see the [QAError class](#).

### See Also

[getLastErrorMsg function](#)

[QAError class](#)

[QAManagerBase](#)

### Returns

The error code.

## getLastErrorMsg function

### Synopsis

```
virtual qa_string QAManagerBase::getLastErrorMsg()
```

### Remarks

The error text associated with the last executed QAManagerBase method.

This method returns null if [getLastError function](#) returns 0. You can retrieve this property after catching a [QAError class](#).

**See Also**

[getLastError function](#)

[QAError class](#)

QAManagerBase

**Returns**

The error message.

## getLongStoreProperty function

**Synopsis**

```
virtual qa_bool QAManagerBase::getLongStoreProperty(  
    qa_const_string name,  
    qa_long * value  
)
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The destination for the long value.

**Remarks**

Gets a long value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

**See Also**

QAManagerBase

**Returns**

True if and only if the operation succeeded.

## getMessage function

**Synopsis**

```
virtual QAMessage * QAManagerBase::getMessage(  
    qa_const_string address  
)
```

**Parameters**

- ◆ **address** The destination.

**Remarks**

Returns the next available [QAMessage class](#) sent to the specified address.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If there is no message available, this call blocks indefinitely until a message is available. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

**See Also**

QAManagerBase

**Returns**

The next [QAMessage class](#), or null if no message is available.

## getMessageBySelector function

**Synopsis**

```
virtual QAMessage * QAManagerBase::getMessageBySelector(  
    qa_const_string address,  
    qa_const_string selector  
)
```

**Parameters**

- ◆ **address** The destination.
- ◆ **selector** The selector.

**Remarks**

Returns the next available [QAMessage class](#) sent to the specified address that satisfies the given selector.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If there is no message available, this call blocks indefinitely until a message is available. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

**See Also**

QAManagerBase

**Returns**

The next [QAMessage class](#), or null if no message is available.

---

## getMessageBySelectorNoWait function

### Synopsis

```
virtual QAMessage * QAManagerBase::getMessageBySelectorNoWait(  
    qa_const_string address,  
    qa_const_string selector  
)
```

### Parameters

- ◆ **address**    The destination.
- ◆ **selector**    The selector.

### Remarks

Returns the next available [QAMessage class](#) sent to the given address that satisfies the given selector.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method returns immediately. Use this method to receive messages synchronously. For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

### See Also

[QAManagerBase](#)

### Returns

the next message, or qa\_null if no message is available.

## getMessageBySelectorTimeout function

### Synopsis

```
virtual QAMessage * QAManagerBase::getMessageBySelectorTimeout(  
    qa_const_string address,  
    qa_const_string selector,  
    qa_long timeout  
)
```

### Parameters

- ◆ **address**    The destination.
- ◆ **selector**    The selector.
- ◆ **timeout**    the maximum time, in milliseconds, to wait

### Remarks

Returns the next available [QAMessage class](#) sent to the given address that satisfies the given selector.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method waits for the specified timeout and then returns. Use

this method to receive messages synchronously. For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

### See Also

QAManagerBase

### Returns

The next [QAMessage class](#), or null if no message is available.

## getMessageNoWait function

### Synopsis

```
virtual QAMessage * QAManagerBase::getMessageNoWait(  
    qa_const_string address  
)
```

### Parameters

◆ **address** The destination.

### Remarks

Returns the next available [QAMessage class](#) sent to the given address.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method returns immediately. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

### See Also

QAManagerBase

### Returns

The next message, or qa\_null if no message is available.

## getMessageTimeout function

### Synopsis

```
virtual QAMessage * QAManagerBase::getMessageTimeout(  
    qa_const_string address,  
    qa_long timeout  
)
```

### Parameters

◆ **address** The destination

- ◆ **timeout** The maximum time, in milliseconds, to wait

**Remarks**

Returns the next available [QAMessage class](#) sent to the given address.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method waits for the specified timeout and then returns. Use this method to receive messages synchronously.

For more information about receiving messages asynchronously (using a message event handler), see [“Receiving messages asynchronously” on page 76](#).

**See Also**

[QAManagerBase](#)

**Returns**

The next [QAMessage class](#), or null if no message is available.

## getMode function

**Synopsis**

```
virtual qa_short QAManagerBase::getMode()
```

**Remarks**

Returns the [QAManager class](#) acknowledgement mode for received messages.

For a list of values, see the [AcknowledgementMode class](#).

[EXPLICIT\\_ACKNOWLEDGEMENT](#) variable and [IMPLICIT\\_ACKNOWLEDGEMENT](#) variable apply to [QAManager class](#) instances; [TRANSACTIONAL](#) variable is the mode for [QATransactionalManager class](#) instances.

**See Also**

[QAManagerBase](#)

**Returns**

the acknowledge mode

**See Also**

[AcknowledgementMode class](#)

## getQueueDepth function

### Synopsis

```
virtual qa_int QAManagerBase::getQueueDepth(  
    qa_const_string address,  
    qa_short filter  
)
```

### Parameters

- ◆ **address** The queue name.
- ◆ **filter** a filter indicating incoming messages, outgoing messages, or all messages.

### Remarks

Returns the depth of a queue, based on a given filter.

The depth of the queue is the number of messages which have not been received (for example, using [getMessage function](#)).

### See Also

[QAManagerBase](#)

### Returns

The number of messages in the queue, or -1 if an error occurs.

### See Also

[QueueDepthFilter class](#)

## getShortStoreProperty function

### Synopsis

```
virtual qa_bool QAManagerBase::getShortStoreProperty(  
    qa_const_string name,  
    qa_short * value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The destination for the short value.

### Remarks

Gets a short value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

### See Also

QAManagerBase

### Returns

True if and only if the operation succeeded.

## getStringStoreProperty function

### Synopsis

```
virtual qa_int QAManagerBase::getStringStoreProperty(  
    qa_const_string name,  
    qa_string address,  
    qa_int maxlen  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **address** The destination for the qa\_string value.
- ◆ **maxlen** The maximum number of qa\_chars of the value to copy, including the null terminator character.

### Remarks

Gets a string value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

### See Also

QAManagerBase

### Returns

The number of non-null qa\_chars actually copied, or -1 if the operation failed.

## nextStorePropertyName function

### Synopsis

```
virtual qa_int QAManagerBase::nextStorePropertyName(  
    qa_store_property_enum_handle h,  
    qa_string buffer,  
    qa_int bufferLen  
)
```

### Parameters

- ◆ **h** A handle returned by `beginEnumStorePropertyNames`.
- ◆ **buffer** The buffer into which to write the property name.
- ◆ **bufferLen** The length of the buffer to store the property name. This length must include space for the null terminator.

### Remarks

Returns the message store property name for the given enumeration.

If there are no more property names, returns -1.

### See Also

`QAManagerBase`

### Returns

The length of the property name, or -1 if there are no more property names. property names

## putMessage function

### Synopsis

```
virtual qa_bool QAManagerBase::putMessage(  
    qa_const_string address,  
    QAMessage * msg  
)
```

### Parameters

- ◆ **address** The destination.
- ◆ **msg** The message.

### Remarks

Puts a message into the queue for the given destination.

### See Also

`QAManagerBase`

### Returns

True if and only if the operation succeeded.

---

## putMessageTimeToLive function

### Synopsis

```
virtual qa_bool QAManagerBase::putMessageTimeToLive(  
    qa_const_string address,  
    QAMessage * msg,  
    qa_long ttl  
)
```

### Parameters

- ◆ **address** The destination.
- ◆ **msg** The message.
- ◆ **ttl** The time-to-live, in milliseconds.

### Remarks

Puts a message into the queue for the given destination and a given time-to-live in milliseconds.

### See Also

QAManagerBase

### Returns

True if and only if the operation succeeded.

## setBooleanStoreProperty function

### Synopsis

```
virtual qa_bool QAManagerBase::setBooleanStoreProperty(  
    qa_const_string name,  
    qa_bool value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The qa\_bool value of the property.

### Remarks

Sets a pre-defined or custom message store property to a boolean value.

You can use this method to set pre-defined or user-defined client. store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

### See Also

QAManagerBase

### Returns

True if and only if the operation succeeded.

## setByteStoreProperty function

### Synopsis

```
virtual qa_bool QAManagerBase::setByteStoreProperty(  
    qa_const_string name,  
    qa_byte value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The qa\_byte value of the property.

### Remarks

Sets a pre-defined or custom message store property to a byte value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

### See Also

QAManagerBase

### Returns

True if and only if the operation succeeded.

## setDoubleStoreProperty function

### Synopsis

```
virtual qa_bool QAManagerBase::setDoubleStoreProperty(  
    qa_const_string name,  
    qa_double value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The qa\_double value of the property.

**Remarks**

Sets a pre-defined or custom message store property to a double value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

**See Also**

QAManagerBase

**Returns**

True if and only if the operation succeeded.

**setFloatStoreProperty function****Synopsis**

```
virtual qa_bool QAManagerBase::setFloatStoreProperty(  
    qa_const_string name,  
    qa_float value  
)
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The qa\_float value of the property.

**Remarks**

Sets a pre-defined or custom message store property to a float value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

**See Also**

QAManagerBase

**Returns**

True if and only if the operation succeeded.

## setIntStoreProperty function

### Synopsis

```
virtual qa_bool QAManagerBase::setIntStoreProperty(  
    qa_const_string name,  
    qa_int value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The qa\_int value of the property.

### Remarks

Sets a pre-defined or custom message store property to a int value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

### See Also

QAManagerBase

### Returns

True if and only if the operation succeeded.

## setLongStoreProperty function

### Synopsis

```
virtual qa_bool QAManagerBase::setLongStoreProperty(  
    qa_const_string name,  
    qa_long value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The qa\_long value of the property.

### Remarks

Sets a pre-defined or custom message store property to a long value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

## See Also

QAManagerBase

## Returns

True if and only if the operation succeeded.

## setMessageListener function

### Synopsis

```
virtual void QAManagerBase::setMessageListener(  
    qa_const_string address,  
    QAMessageListener * listener  
)
```

### Parameters

- ◆ **address** The destination address that the listener applies to.
- ◆ **listener** The message listener to associate with destination address.

### Remarks

Sets a message listener class to receive QAnywhere messages asynchronously.

The listener is an instance of a class implementing [onMessage function](#), the only method defined in the [QAMessageListener class](#) interface. [onMessage function](#) accepts a single [QAMessage class](#) parameter.

The setMessageListener address parameter specifies a local queue name used to receive the message. You can only have one listener assigned to a given queue. If you want to listen for QAnywhere system messages, including push notifications and network status changes, specify "system" as the queue name. Use this method to receive message asynchronously.

For more information, see [“Receiving messages asynchronously” on page 76](#) and [“System queue” on page 50](#).

## See Also

QAManagerBase

## setMessageListenerBySelector function

### Synopsis

```
virtual void QAManagerBase::setMessageListenerBySelector(  
    qa_const_string address,  
    qa_const_string selector,  
    QAMessageListener * listener  
)
```

**Parameters**

- ◆ **address** The destination address that the listener applies to.
- ◆ **selector** The selector to be used to filter the messages to be received.
- ◆ **listener** The message listener to associate with destination address.

**Remarks**

Sets a message listener class to receive QAnywhere messages asynchronously, with a message selector.

The listener is an instance of a class implementing [onMessage function](#), the only method defined in the [QAMessageListener class](#) interface. [onMessage function](#) accepts a single [QAMessage class](#) parameter.

The `setMessageListener` address parameter specifies a local queue name used to receive the message. You can only have one listener assigned to a given queue. The selector parameter specifies a selector to be used to filter the messages to be received on the given address. If you want to listen for QAnywhere system messages, including push notifications and network status changes, specify "system" as the queue name. Use this method to receive message asynchronously.

For more information, see [“Receiving messages asynchronously” on page 76](#) and [“System queue” on page 50](#).

**See Also**

[QAManagerBase](#)

## setProperty function

**Synopsis**

```
virtual qa_bool QAManagerBase::setProperty(  
    qa_const_string name,  
    qa_const_string value  
)
```

**Parameters**

- ◆ **name** The pre-defined or custom QAnywhere Manager configuration property name.
- ◆ **value** The value of the QAnywhere Manager configuration property.

**Remarks**

Allows you to set QAnywhere Manager configuration properties programmatically.

You can use this method to override default QAnywhere Manager configuration properties by specifying a property name and value.

For a list of QAnywhere Manager configuration properties, see [“QAnywhere manager configuration properties” on page 62](#).

You can also set QAnywhere Manager configuration properties using a properties file and the [createQAManager function](#).

For more information, see [“Setting QAnywhere manager configuration properties in a file” on page 62](#).

*Note:* you must set required properties before calling [open function](#) or [open function](#).

**See Also**

QAManagerBase

**Returns**

True if and only if the operation succeeded.

## setShortStoreProperty function

**Synopsis**

```
virtual qa_bool QAManagerBase::setShortStoreProperty(  
    qa_const_string name,  
    qa_short value  
)
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The qa\_short value of the property.

**Remarks**

Sets a pre-defined or custom message store property to a short value.

You can use this method to set pre-defined or user-defined client store properties. For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see [“Client message store properties” on page 215](#).

**See Also**

QAManagerBase

**Returns**

True if and only if the operation succeeded.

## setStringStoreProperty function

**Synopsis**

```
virtual qa_bool QAManagerBase::setStringStoreProperty(  
    qa_const_string name,  
    qa_const_string value  
)
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The qa\_string value of the property.

### Remarks

Sets a pre-defined or custom message store property to a string value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [MessageStoreProperties class](#).

For more information, see “[Client message store properties](#)” on page 215.

### See Also

[QAManagerBase](#)

### Returns

True if and only if the operation succeeded.

## start function

### Synopsis

```
virtual qa_bool QAManagerBase::start()
```

### Remarks

Starts the QAManagerBase for receiving incoming messages in message listeners.

The QAManagerBase does not need to be started if there are no message listeners set, ie. if messages are received with the getMessage methods. It is not recommended to use the getMessage methods as well as message listeners for receiving messages, one should use one or the other of the asynchronous (message listener) or synchronous (getMessage) models. Any calls to start beyond the first without an intervening [stop function](#) call are ignored.

### See Also

[stop function](#)

[QAManagerBase](#)

### Returns

True if and only if the operation succeeded.

## stop function

### Synopsis

```
virtual qa_bool QAManagerBase::stop()
```

**Remarks**

Stops the QAManagerBase's reception of incoming messages.

The messages are not lost. They are not received until the manager is started again. Any calls to stop beyond the first without an intervening [start function](#) are ignored.

**See Also**

[start function](#)

QAManagerBase

**Returns**

True if and only if the operation succeeded.

## triggerSendReceive function

**Synopsis**

```
virtual qa_bool QAManagerBase::triggerSendReceive()
```

**Remarks**

Causes a synchronization with the QAnywhere message server, uploading any messages addressed to other clients, and downloading any messages addressed to the local client.

QAManagerBase triggerSendReceive results in immediate message synchronization between a QAnywhere Agent and the central messaging server. A manual TriggerSendReceive call results in immediate message transmission, independent of the QAnywhere Agent transmission policies. QAnywhere Agent transmission policies determine how message transmission occurs. For example, message transmission can occur automatically at regular intervals, when your client receives a push notification, or when you call the [putMessage function](#) to send a message.

For more information, see [“Determining when message transmission should occur on the client” on page 36](#).

**See Also**

[putMessage function](#)

QAManagerBase

**Returns**

True if and only if the operation succeeded.

## QAManagerFactory class

### Synopsis

```
public QAManagerFactory
```

### Remarks

This class acts as a factory class for creating [QATransactionalManager class](#) and [QAManager class](#) objects.

You can only have one instance of QAManagerFactory.

### Members

All members of QAManagerFactory, including all inherited members.

- ◆ [“createQAManager function” on page 462](#)
- ◆ [“createQATransactionalManager function” on page 463](#)
- ◆ [“deleteQAManager function” on page 463](#)
- ◆ [“deleteQATransactionalManager function” on page 464](#)
- ◆ [“getLastError function” on page 464](#)
- ◆ [“getLastErrorMsg function” on page 464](#)

## createQAManager function

### Synopsis

```
virtual QAManager * QAManagerFactory::createQAManager(  
    qa_const_string iniFile  
)
```

### Parameters

- ◆ **iniFile** The path of the properties file.

### Remarks

Returns a new [QAManager class](#) instance with the specified properties.

If the properties file parameter is null, the [QATransactionalManager class](#) is created using default properties. You can use the [setProperty function](#) to set [QATransactionalManager class](#) properties programmatically after you create the instance.

For a list of [QAManagerBase class](#) properties, see [“QAnywhere manager configuration properties” on page 62](#).

### See Also

[QAManager class](#)

### Returns

The [QAManager class](#) instance.

## createQATransactionalManager function

### Synopsis

```
virtual QATransactionalManager * QAManagerFactory::createQATransactionalManager(  
    qa_const_string iniFile  
)
```

### Parameters

- ◆ **iniFile** The path of the properties file.

### Remarks

Returns a new [QAManager class](#) instance with the specified properties.

If the properties file parameter is null, the [QAManager class](#) is created using default properties. You can use the [setProperty function](#) to set [QAManager class](#) properties programmatically after you create the instance.

For a list of [QAManagerBase class](#) properties, see “[QAnywhere manager configuration properties](#)” on page 62.

### See Also

[QATransactionalManager class](#)

### Returns

The [QATransactionalManager class](#) instance.

## deleteQAManager function

### Synopsis

```
virtual void QAManagerFactory::deleteQAManager(  
    QAManager * mgr  
)
```

### Parameters

- ◆ **mgr** The “[QAManager class](#)” on page 427 instance to destroy.

### Remarks

Destroys a [QAManager class](#), freeing its resources.

It is not necessary to use this method, since all created [QAManager's](#) are destroyed when [QAnywhereFactory\\_term\(\)](#) is called. It is provided as a convenience for when it is desirable to free resources in a timely manner. “[Shutting down QAnywhere](#)” on page 88

## deleteQATransactionalManager function

### Synopsis

```
virtual void QAManagerFactory::deleteQATransactionalManager(  
    QATransactionalManager * mgr  
)
```

### Parameters

◆ **mgr** The “[QATransactionalManager class](#)” on page 492 instance to destroy.

### Remarks

Destroys a [QATransactionalManager class](#), freeing its resources.

It is not necessary to use this method, since all created QATransactionalManager's are destroyed when QAnywhereFactory\_term() is called. It is provided as a convenience for when it is desirable to free resources in a timely manner.

For more information, see “[Shutting down QAnywhere](#)” on page 88

## getLastError function

### Synopsis

```
virtual qa_int QAManagerFactory::getLastError()
```

### Remarks

The error code associated with the last executed QAManagerFactory method.

0 indicates no error.

For a list of values, see the [QAEError class](#).

### See Also

[getLastErrorMsg function](#)

[QAEError class](#)

### Returns

The error code.

## getLastErrorMsg function

### Synopsis

```
virtual qa_string QAManagerFactory::getLastErrorMsg()
```

### Remarks

The error text associated with the last executed QAManagerFactory method.

This method returns null if [getLastError function](#) returns 0. You can retrieve this property after catching a [QLError class](#).

**See Also**

[getLastError function](#)

[QLError class](#)

**Returns**

The error message.

## QAMessage class

### Synopsis

```
public QAMessage
```

### Derived classes

- ◆ [“QABinaryMessage class” on page 404](#)
- ◆ [“QATextMessage class” on page 488](#)

### Remarks

QAMessage provides an interface to set message properties and header fields.

The derived classes [QABinaryMessage class](#) and [QATextMessage class](#) provide specialized functions to read and write to the message body. You can use QAMessage functions to set predefined or custom message properties.

For a list of pre-defined property names, see the [MessageProperties class](#).

For more information about setting message properties and header fields, see [“Message headers and message properties” on page 206](#).

### Members

All members of QAMessage, including all inherited members.

- ◆ [“beginEnumPropertyNames function” on page 468](#)
- ◆ [“castToBinaryMessage function” on page 468](#)
- ◆ [“castToTextMessage function” on page 468](#)
- ◆ [“clearProperties function” on page 469](#)
- ◆ [“DEFAULT\\_PRIORITY variable” on page 467](#)
- ◆ [“DEFAULT\\_TIME\\_TO\\_LIVE variable” on page 467](#)
- ◆ [“endEnumPropertyNames function” on page 469](#)
- ◆ [“getAddress function” on page 469](#)
- ◆ [“getBooleanProperty function” on page 470](#)
- ◆ [“getByteProperty function” on page 470](#)
- ◆ [“getDoubleProperty function” on page 471](#)
- ◆ [“getExpiration function” on page 471](#)
- ◆ [“getFloatProperty function” on page 472](#)
- ◆ [“getInReplyToID function” on page 472](#)
- ◆ [“getIntProperty function” on page 473](#)
- ◆ [“getLongProperty function” on page 473](#)
- ◆ [“getMessageID function” on page 474](#)
- ◆ [“getPriority function” on page 474](#)
- ◆ [“getPropertyType function” on page 475](#)
- ◆ [“getRedelivered function” on page 475](#)
- ◆ [“getReplyToAddress function” on page 476](#)
- ◆ [“getShortProperty function” on page 476](#)
- ◆ [“getStringProperty function” on page 477](#)

- ◆ “getStringProperty function” on page 477
- ◆ “getTimestamp function” on page 478
- ◆ “getTimestampAsString function” on page 479
- ◆ “nextPropertyName function” on page 479
- ◆ “propertyExists function” on page 480
- ◆ “setAddress function” on page 480
- ◆ “setBooleanProperty function” on page 480
- ◆ “setByteProperty function” on page 481
- ◆ “setDoubleProperty function” on page 481
- ◆ “setFloatProperty function” on page 482
- ◆ “setInReplyToID function” on page 482
- ◆ “setIntProperty function” on page 483
- ◆ “setLongProperty function” on page 483
- ◆ “setMessageID function” on page 484
- ◆ “setPriority function” on page 484
- ◆ “setRedelivered function” on page 484
- ◆ “setReplyToAddress function” on page 485
- ◆ “setShortProperty function” on page 485
- ◆ “setStringProperty function” on page 486
- ◆ “setTimestamp function” on page 486

## DEFAULT\_PRIORITY variable

### Synopsis

```
const qa_int QAMessage::DEFAULT_PRIORITY
```

### Remarks

The default message priority.

This value is 4. This is normal priority as values 0-4 are gradations of normal priority and values 5-9 are gradations of expedited priority.

## DEFAULT\_TIME\_TO\_LIVE variable

### Synopsis

```
const qa_long QAMessage::DEFAULT_TIME_TO_LIVE
```

### Remarks

The default message time-to-live value.

This value is 0, which indicates that the message does not expire.

## beginEnumPropertyNames function

### Synopsis

```
virtual qa_property_enum_handle QAMessage::beginEnumPropertyNames()
```

### Remarks

Begins an enumeration of message property names.

The handle returned by this method is supplied to `nextPropertyName`. This method and `nextPropertyName` can be used to enumerate the message property names at the time this method was called. Message properties cannot be set between `beginEnumPropertyNames` and `endEnumPropertyNames`.

### Returns

A handle that is supplied to `nextPropertyName`.

## castToBinaryMessage function

### Synopsis

```
virtual QABinaryMessage * QAMessage::castToBinaryMessage()
```

### Remarks

Casts this `QAMessage` to a [QABinaryMessage class](#).

You can also use the conversion operator to convert this `QAMessage` to a [QABinaryMessage class](#).

To convert a `QAMessage` to a [QABinaryMessage class](#) using the conversion operator, do the following:

```
QAMessage *msg;  
QABinaryMessage *bmsg;  
...  
bmsg = (QABinaryMessage *)(*msg);
```

### Returns

A pointer to the [QABinaryMessage class](#), or NULL if this message is not an instance of [QABinaryMessage class](#).

## castToTextMessage function

### Synopsis

```
virtual QATextMessage * QAMessage::castToTextMessage()
```

### Remarks

Casts this `QAMessage` to a [QATextMessage class](#).

You can also use the conversion operator to convert this `QAMessage` to a [QATextMessage class](#).

For example, to convert a QAMessage to a [QATextMessage class](#) using the conversion operator, do the following:

```
QAMessage *msg;  
QATextMessage *bmsg;  
...  
bmsg = (QATextMessage *) (*msg);
```

### Returns

A pointer to the [QATextMessage class](#), or NULL if this message is not an instance of [QATextMessage class](#).

## clearProperties function

### Synopsis

```
virtual void QAMessage::clearProperties()
```

### Remarks

Clears a message's properties.

*Note:* The message's header fields and body are not cleared.

## endEnumPropertyNames function

### Synopsis

```
virtual void QAMessage::endEnumPropertyNames(  
    qa_property_enum_handle h  
)
```

### Parameters

◆ **h** A handle returned by beginEnumPropertyNames.

### Remarks

Frees the resources associated with a message property name enumeration.

## getAddress function

### Synopsis

```
virtual qa_const_string QAMessage::getAddress()
```

### Remarks

Gets the destination address for the QAMessage instance.

When a message is sent, this field is ignored. After completion of the send method, the field holds the destination address specified in [putMessage function](#).

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### Returns

The destination address.

## getBooleanProperty function

### Synopsis

```
virtual qa_bool QAMessage::getBooleanProperty(  
    qa_const_string name,  
    qa_bool * value  
)
```

### Parameters

- ◆ **name** The name of the property to get.
- ◆ **value** The destination for the qa\_bool value.

### Remarks

Gets the value of the qa\_bool property with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#)

### Returns

True if and only if the operation succeeded.

## getBytesProperty function

### Synopsis

```
virtual qa_byte QAMessage::getBytesProperty(  
    qa_const_string name,  
    qa_byte * value  
)
```

### Parameters

- ◆ **name** The name of the property to get.
- ◆ **value** The destination for the qa\_byte value.

### Remarks

Gets the value of the qa\_byte property with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See Also**

[MessageProperties class](#)

**Returns**

True if and only if the operation succeeded.

## getDoubleProperty function

**Synopsis**

```
virtual qa_bool QAMessage::getDoubleProperty(  
    qa_const_string name,  
    qa_double * value  
)
```

**Parameters**

- ◆ **name**    The name of the property to get.
- ◆ **value**    The destination for the qa\_double value.

**Remarks**

Gets the value of the qa\_double property with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See Also**

[MessageProperties class](#)

**Returns**

True if and only if the operation succeeded.

## getExpiration function

**Synopsis**

```
virtual qa_long QAMessage::getExpiration()
```

**Remarks**

Gets the message's expiration time.

When a message is sent, the Expiration header field is left unassigned. After the send method completes, the Expiration header holds the expiration time of the message.

This property is read-only because the expiration time of a message is set by adding the time-to-live argument of `QAManagerBase::PutMessageTimeToLive` to the current time.

The expiration time is in units that are natural for the platform. For Windows/PocketPC platforms, expiration is a `SYSTEMTIME`, converted to a `FILETIME`, which is copied to an `qa_long` value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### Returns

The expiration time.

### See Also

[getTimestamp function](#)

## getFloatProperty function

### Synopsis

```
virtual qa_bool QAMessage::getFloatProperty(  
    qa_const_string name,  
    qa_float * value  
)
```

### Parameters

- ◆ **name** The name of the property to get.
- ◆ **value** The destination for the `qa_float` value.

### Remarks

Gets the value of the `qa_float` property with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#)

### Returns

True if and only if the operation succeeded.

## getInReplyToID function

### Synopsis

```
virtual qa_const_string QAMessage::getInReplyToID()
```

**Remarks**

Gets the ID of the message that this message is in reply to.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**Returns**

The In-Reply-To ID.

## getIntProperty function

**Synopsis**

```
virtual qa_bool QAMessage::getIntProperty(  
    qa_const_string name,  
    qa_int * value  
)
```

**Parameters**

- ◆ **name** The name of the property to get.
- ◆ **value** The destination for the qa\_int value.

**Remarks**

Gets the value of the qa\_int property with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See Also**

[MessageProperties class](#)

**Returns**

True if and only if the operation succeeded.

## getLongProperty function

**Synopsis**

```
virtual qa_bool QAMessage::getLongProperty(  
    qa_const_string name,  
    qa_long * value  
)
```

**Parameters**

- ◆ **name** The name of the property to get.
- ◆ **value** The destination for the qa\_long value.

### Remarks

Gets the value of the `qa_long` property with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#)

### Returns

True if and only if the operation succeeded.

## getMessageID function

### Synopsis

```
virtual qa_const_string QAMessage::getMessageID()
```

### Remarks

Gets the message ID.

The MessageID header field contains a value that uniquely identifies each message sent by the QAnywhere client.

When a message is sent using [putMessage function](#), the MessageID header is null and can be ignored. When the send method returns, it contains an assigned value.

A MessageID is a `qa_string` value that should function as a unique key for identifying messages in a historical repository.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### Returns

The message ID.

## getPriority function

### Synopsis

```
virtual qa_int QAMessage::getPriority()
```

### Remarks

Gets the message priority level.

The QAnywhere client API defines ten levels of priority value, with 0 as the lowest priority and 9 as the highest. Clients should consider priorities 0-4 as gradations of normal priority and priorities 5-9 as gradations of expedited priority.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**Returns**

The message priority.

## getPropertyType function

**Synopsis**

```
virtual qa_short QAMessage::getPropertyType(
    qa_const_string name
)
```

**Parameters**

◆ **name** The name of the property.

**Remarks**

Returns the type of a property with the given name.

One of PROPERTY\_TYPE\_BOOLEAN, PROPERTY\_TYPE\_BYTE, PROPERTY\_TYPE\_SHORT, PROPERTY\_TYPE\_INT, PROPERTY\_TYPE\_LONG, PROPERTY\_TYPE\_FLOAT, PROPERTY\_TYPE\_DOUBLE, PROPERTY\_TYPE\_STRING, PROPERTY\_TYPE\_UNKNOWN.

**Returns**

The type of the property.

## getRedelivered function

**Synopsis**

```
virtual qa_bool QAMessage::getRedelivered()
```

**Remarks**

Indicates whether the message has been previously received but not acknowledged.

The Redelivered header is set by a receiving [QAManager class](#) when it detects that a message being received was received before.

For example, an application receives a message using a [QAManager class](#) opened with [EXPLICIT\\_ACKNOWLEDGEMENT](#) variable, and shuts down without acknowledging the message. When the application starts again and receives the same message the Redelivered header is true.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## Returns

True if and only if the message was redelivered.

## getReplyToAddress function

### Synopsis

```
virtual qa_const_string QAMessage::getReplyToAddress()
```

### Remarks

Gets the address to which a reply to this message should be sent.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### Returns

The reply-to address.

## getShortProperty function

### Synopsis

```
virtual qa_bool QAMessage::getShortProperty(  
    qa_const_string name,  
    qa_short * value  
)
```

### Parameters

- ◆ **name** The name of the property to get.
- ◆ **value** The destination for the qa\_short value.

### Remarks

Gets the value of the qa\_short property with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#)

### Returns

True if and only if the operation succeeded.

## getStringProperty function

### Synopsis

```
virtual qa_int QAMessage::getStringProperty(  
    qa_const_string name,  
    qa_string dest,  
    qa_int maxlen  
)
```

### Parameters

- ◆ **name** The name of the property to get.
- ◆ **dest** The destination for the qa\_string value.
- ◆ **maxlen** The maximum number of qa\_chars of the value to copy. This value includes the null terminator qa\_char.

### Remarks

Gets the value of the qa\_string property with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#)

### Returns

The number of non-null qa\_chars actually copied, or -1 if the operation failed.

## getStringProperty function

### Synopsis

```
virtual qa_int QAMessage::getStringProperty(  
    qa_const_string name,  
    qa_int offset,  
    qa_string dest,  
    qa_int maxlen  
)
```

### Parameters

- ◆ **name** The name of the property to get.
- ◆ **offset** The starting offset into the property value from which to copy.
- ◆ **dest** The destination for the qa\_string value.
- ◆ **maxlen** The maximum number of qa\_chars of the value to copy. This value includes the null terminator qa\_char.

**Remarks**

Gets the value of the qa\_string property (starting at offset) with the specified name.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See Also**

[MessageProperties class](#)

**Returns**

The number of non-null qa\_chars actually copied, or -1 if the operation failed.

## getTimestamp function

**Synopsis**

```
virtual qa_long QAMessage::getTimestamp()
```

**Remarks**

Gets the message timestamp.

This Timestamp header field contains the time a message was created. It is a coordinated universal time (UTC). It is not the time the message was actually transmitted, because the actual send may occur later due to transactions or other client-side queuing of messages. It is in units that are natural for the platform. For Windows/PocketPC platforms, the timestamp is a SYSTEMTIME, converted to a FILETIME, which is copied to a qa\_long value.

To convert a timestamp ts to SYSTEMTIME for displaying to a user, run the following code:

```
SYSTEMTIME stime;  
FILETIME ftime;  
ULARGE_INTEGER time;  
time.QuadPart = ts;  
memcpy(&ftime, &time, sizeof(FILETIME));  
FileTimeToSystemTime(&ftime, &stime);
```

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**Returns**

The message timestamp.

## getTimestampAsString function

### Synopsis

```
virtual qa_int QAMessage::getTimestampAsString(  
    qa_string buffer,  
    qa_int bufferLen  
)
```

### Parameters

- ◆ **buffer** The buffer for the formatted timestamp.
- ◆ **bufferLen** The size of the buffer.

### Remarks

Gets the message timestamp as a formatted string.

The format is: "dow, MMM dd, yyyy hh:mm:ss.nnn GMT".

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### Returns

The number of non-null qa\_chars written to the buffer.

## nextPropertyName function

### Synopsis

```
virtual qa_int QAMessage::nextPropertyName(  
    qa_property_enum_handle h,  
    qa_string buffer,  
    qa_int bufferLen  
)
```

### Parameters

- ◆ **h** A handle returned by beginEnumPropertyNames.
- ◆ **buffer** The buffer into which to write the property name.
- ◆ **bufferLen** The length of the buffer to store the property name. This length must include space for the null terminator

### Remarks

Returns the message property name for the given enumeration, returning -1 if there are no more property names.

### Returns

The length of the property name, or -1 if there are no more property names.

## propertyExists function

### Synopsis

```
virtual qa_bool QAMessage::propertyExists(  
    qa_const_string name  
)
```

### Parameters

◆ **name** The name of the property.

### Remarks

Indicates whether a property value exists.

### Returns

True if and only if the property exists.

## setAddress function

### Synopsis

```
virtual void QAMessage::setAddress(  
    qa_const_string destination  
)
```

### Parameters

◆ **destination** The destination address.

### Remarks

Sets the destination address for this message.

This method can be used to change the value for a message that has been received.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## setBooleanProperty function

### Synopsis

```
virtual void QAMessage::setBooleanProperty(  
    qa_const_string name,  
    qa_bool value  
)
```

### Parameters

◆ **name** the name of the property to set.

- ◆ **value** the qa\_bool value of the property.

### Remarks

Sets the qa\_bool property with the specified name to the specified value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#)

## setByteProperty function

### Synopsis

```
virtual void QAMessage::setByteProperty(  
    qa_const_string name,  
    qa_byte value  
)
```

### Parameters

- ◆ **name** The name of the property to set.
- ◆ **value** The qa\_byte value of the property.

### Remarks

Sets a qa\_byte property with the specified name to the specified value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#)

## setDoubleProperty function

### Synopsis

```
virtual void QAMessage::setDoubleProperty(  
    qa_const_string name,  
    qa_double value  
)
```

### Parameters

- ◆ **name** The name of the property to set.
- ◆ **value** The qa\_double value of the property.

### Remarks

Sets the `qa_double` property with the specified name to the specified value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#).

## setFloatProperty function

### Synopsis

```
virtual void QAMessage::setFloatProperty(  
    qa_const_string name,  
    qa_float value  
)
```

### Parameters

- ◆ **name** The name of the property to set.
- ◆ **value** The `qa_float` value of the property.

### Remarks

Sets the `qa_float` property with the specified name to the specified value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#).

## setInReplyToID function

### Synopsis

```
virtual void QAMessage::setInReplyToID(  
    qa_const_string id  
)
```

### Parameters

- ◆ **id** The In-Reply-To ID.

### Remarks

Sets the In-Reply-To ID for the message.

A client can use the `InReplyToID` header field to link one message with another. A typical use is to link a response message with its request message.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## setIntProperty function

### Synopsis

```
virtual void QAMessage::setIntProperty(  
    qa_const_string name,  
    qa_int value  
)
```

### Parameters

- ◆ **name** The name of the property to set.
- ◆ **value** The `qa_int` value of the property.

### Remarks

Sets the `qa_int` property with the specified name to the specified value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

### See Also

[MessageProperties class](#).

## setLongProperty function

### Synopsis

```
virtual void QAMessage::setLongProperty(  
    qa_const_string name,  
    qa_long value  
)
```

### Parameters

- ◆ **name** The name of the property to set.
- ◆ **value** The `qa_long` value of the property.

### Remarks

Sets the `qa_long` property with the specified name to the specified value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## See Also

[MessageProperties class](#).

## setMessageID function

### Synopsis

```
virtual void QAMessage::setMessageID(  
    qa_const_string id  
)
```

### Parameters

◆ **id** The message ID.

### Remarks

Sets the message ID.

This method can be used to change the value for a message that has been received.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## setPriority function

### Synopsis

```
virtual void QAMessage::setPriority(  
    qa_int priority  
)
```

### Parameters

◆ **priority** The message priority.

### Remarks

Sets the priority level for this message.

This method can be used to change the value for a message that has been received.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## setRedelivered function

### Synopsis

```
virtual void QAMessage::setRedelivered(  
    qa_bool redelivered  
)
```

**Parameters**

- ◆ **redelivered** The redelivered indication.

**Remarks**

Sets an indication of whether this message was redelivered.

This method can be used to change the value for a message that has been received.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## setReplyToAddress function

**Synopsis**

```
virtual void QAMessage::setReplyToAddress(  
    qa_const_string replyTo  
)
```

**Parameters**

- ◆ **replyTo** The reply-to address.

**Remarks**

Sets the address to which a reply to this message should be sent.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

## setShortProperty function

**Synopsis**

```
virtual void QAMessage::setShortProperty(  
    qa_const_string name,  
    qa_short value  
)
```

**Parameters**

- ◆ **name** The name of the property to set.
- ◆ **value** The qa\_short value of the property.

**Remarks**

Sets the qa\_short property with the specified name to the specified value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See Also**

[MessageProperties class](#).

**setStringProperty function****Synopsis**

```
virtual void QAMessage::setStringProperty(  
    qa_const_string name,  
    qa_const_string value  
)
```

**Parameters**

- ◆ **name** The name of the property to set.
- ◆ **value** The qa\_string value of the property.

**Remarks**

Sets a qa\_string property with the specified name to the specified value.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See Also**

[MessageProperties class](#).

**setTimestamp function****Synopsis**

```
virtual void QAMessage::setTimestamp(  
    qa_long timestamp  
)
```

**Parameters**

- ◆ **timestamp** The message timestamp, a coordinated universal time (UTC).

**Remarks**

Sets the message timestamp.

This method can be used to change the value for a message that has been received.

For more information about getting and setting message headers and properties, see [“Message headers and message properties” on page 206](#).

**See Also**

[getTimestamp function](#)

## QAMessageListener class

### Synopsis

```
public QAMessageListener
```

### Remarks

A QAMessageListener object is used to receive asynchronously delivered messages.

### Members

All members of QAMessageListener, including all inherited members.

- ◆ [“onMessage function” on page 487](#)
- ◆ [“~QAMessageListener function” on page 487](#)

## onMessage function

### Synopsis

```
virtual void QAMessageListener::onMessage(  
    QAMessage * message  
)
```

### Parameters

- ◆ **message** the message passed to the listener

### Remarks

Passes a message to the listener.

## ~QAMessageListener function

### Synopsis

```
virtual QAMessageListener::~~QAMessageListener()
```

### Remarks

Virtual destructor.

## QATextMessage class

### Synopsis

public **QATextMessage**

### Base classes

- ◆ “[QAMessage class](#)” on page 466

### Remarks

QATextMessage inherits from the [QAMessage class](#) and adds a text message body.

QATextMessage provides methods to read from and write to the text message body.

When the message is first created, the body of the message is in write-only mode. After a message has been sent, the client that sent it can retain and modify it without affecting the message that has been sent. The same message object can be sent multiple times.

When a message is received, the provider has called [reset function](#) so that the message body is in read-only mode and reading of values starts from the beginning of the message body. If a client attempts to write a message in read-only mode, a COMMON\_MSG\_NOT\_WRITEABLE\_ERROR is set.

### See Also

[QABinaryMessage class](#)

## getText function

### Synopsis

```
virtual qa_string QATextMessage::getText()
```

### Remarks

Gets the string containing this message's data.

The default value is null.

If the message exceeds the maximum size specified by the [QAManager class](#) `MAX_IN_MEMORY_MESSAGE_SIZE` property, this function returns null. In this case, use the [readText function](#) to read the text.

For more information about [QAManager class](#) properties, see “[QAnywhere manager configuration properties](#)” on page 62.

## Returns

the string containing the message's data.

## getTextLength function

### Synopsis

```
virtual qa_long QATextMessage::getTextLength()
```

### Remarks

Returns the text length.

*Note:* If the text length is non-zero and [getText function](#) returns `qa_null` then the text does not fit in memory, and must be read in pieces using the `readText`.

## readText function

### Synopsis

```
virtual qa_int QATextMessage::readText(  
    qa_string string,  
    qa_int length  
)
```

### Parameters

- ◆ **string** The destination for the text.
- ◆ **length** The maximum number of `qa_chars` to read into the destination. buffer, including the null termination character.

### Remarks

Reads the requested length of text from the current text position into a buffer.

### Returns

The actual number of non-null `qa_chars` read, or -1 if the entire text stream has been read.

## reset function

### Synopsis

```
virtual void QATextMessage::reset()
```

### Remarks

Repositions the current text position to the beginning.

## setText function

### Synopsis

```
virtual void QATextMessage::setText(  
    qa_const_string string  
)
```

### Parameters

- ◆ **string** A string containing the message data to set.

### Remarks

Sets the string containing this message's data.

## writeText function

### Synopsis

```
virtual void QATextMessage::writeText(  
    qa_const_string string,  
    qa_int offset,  
    qa_int length  
)
```

### Parameters

- ◆ **string** The source text to concatenate.
- ◆ **offset** The offset into the source text at which to start reading.
- ◆ **length** The number of qa\_chars of the source text to read.

### Remarks

Concatenates text to the current text.

## ~QATextMessage function

### Synopsis

```
virtual QATextMessage::~QATextMessage()
```

### Remarks

Virtual destructor.

# QATransactionalManager class

## Synopsis

public QATransactionalManager

## Base classes

- ◆ [“QAManagerBase class” on page 432](#)

## Remarks

This class is the manager for transactional messaging.

The QATransactionalManager class derives from [QAManagerBase class](#) and manages transactional QAnywhere messaging operations.

For a detailed description of derived behavior, see [QAManagerBase class](#).

The QATransactionalManager can only be used for transactional acknowledgement. Use the [commit function](#) to commit all [putMessage function](#) and [getMessage function](#) invocations.

For more information, see [“Implementing transactional messaging” on page 68](#)

## See Also

QATransactionalManager.

## Members

All members of QATransactionalManager, including all inherited members.

## commit function

### Synopsis

```
virtual qa_bool QATransactionalManager::commit()
```

### Remarks

Commits the current transaction and begins a new transaction.

This method commits all [putMessage function](#) and [getMessage function](#) invocations.

*Note:* The first transaction begins with the call to [open function](#).

### See Also

QATransactionalManager

### Returns

True if and only if the commit operation was successful.

## open function

### Synopsis

```
virtual qa_bool QATransactionalManager::open()
```

### Remarks

Opens a QATransactionalManager instance.

The open method must be the first method called after creating a manager.

### See Also

QATransactionalManager

### Returns

True if and only if the operation was successful.

## rollback function

### Synopsis

```
virtual qa_bool QATransactionalManager::rollback()
```

### Remarks

Rolls back the current transaction and begins a new transaction.

This method rolls back all uncommitted [putMessage function](#) and [getMessage function](#) invocations.

### See Also

QATransactionalManager

### Returns

True if and only if the open operation was successful.

## ~QATransactionalManager function

### Synopsis

```
virtual QATransactionalManager::~QATransactionalManager()
```

**Remarks**

Virtual destructor.

## QueueDepthFilter class

### Synopsis

```
public QueueDepthFilter
```

### Remarks

QueueDepthFilter values for Queue depth APIs of [QAManagerBase class](#).

### Members

All members of QueueDepthFilter, including all inherited members.

- ◆ [“ALL variable” on page 496](#)
- ◆ [“INCOMING variable” on page 496](#)
- ◆ [“OUTGOING variable” on page 496](#)

## ALL variable

### Synopsis

```
const qa_short QueueDepthFilter::ALL
```

### Remarks

Count both incoming and outgoing messages.

System messages and expired messages are not included in any queue depth counts.

## INCOMING variable

### Synopsis

```
const qa_short QueueDepthFilter::INCOMING
```

### Remarks

Count only incoming messages.

An incoming message is defined as a message whose originator is different than the agent ID of the message store.

## OUTGOING variable

### Synopsis

```
const qa_short QueueDepthFilter::OUTGOING
```

**Remarks**

Count only outgoing messages.

An outgoing message is defined as a message whose originator is the agent ID of the message store, and whose destination is not the agent ID of the message store.

## StatusCodes class

### Synopsis

public **StatusCodes**

### Remarks

This interface defines a set of codes for the status of a message.

### Members

All members of StatusCodes, including all inherited members.

- ◆ [“CANCELLED variable” on page 498](#)
- ◆ [“EXPIRED variable” on page 498](#)
- ◆ [“FINAL variable” on page 499](#)
- ◆ [“LOCAL variable” on page 499](#)
- ◆ [“PENDING variable” on page 499](#)
- ◆ [“RECEIVED variable” on page 499](#)
- ◆ [“RECEIVING variable” on page 500](#)
- ◆ [“TRANSMITTED variable” on page 500](#)
- ◆ [“TRANSMITTING variable” on page 500](#)
- ◆ [“UNRECEIVABLE variable” on page 500](#)
- ◆ [“UNTRANSMITTED variable” on page 501](#)

## CANCELLED variable

### Synopsis

const qa\_int **StatusCodes::CANCELLED**

### Remarks

The message has been cancelled.

This code has value 40. This code applies to the `MMessageProperties::STATUS`.

## EXPIRED variable

### Synopsis

const qa\_int **StatusCodes::EXPIRED**

### Remarks

The message has expired, i.e.

the message was not received before its expiration time passed. This code has value 30. This code applies to the `MMessageProperties::STATUS`.

## FINAL variable

### Synopsis

```
const qa_int StatusCodes::FINAL
```

### Remarks

The message has achieved a final state.

This code has value 20. This code applies to the MMessageProperties::STATUS.

## LOCAL variable

### Synopsis

```
const qa_int StatusCodes::LOCAL
```

### Remarks

The message is addressed to the local message store and will not be transmitted to the server.

This code has value 2. This code applies to the MMessageProperties::TRANSMISSION\_STATUS.

## PENDING variable

### Synopsis

```
const qa_int StatusCodes::PENDING
```

### Remarks

The message has been sent but not received.

This code has value 1. This code applies to the MMessageProperties::STATUS.

## RECEIVED variable

### Synopsis

```
const qa_int StatusCodes::RECEIVED
```

### Remarks

The message has been received and acknowledged by the receiver.

This code has value 60. This code applies to the MMessageProperties::STATUS.

## RECEIVING variable

### Synopsis

```
const qa_int StatusCodes::RECEIVING
```

### Remarks

The message is in the process of being received, or it was received but not acknowledged.

This code has value 10. This code applies to the MMessageProperties::STATUS.

## TRANSMITTED variable

### Synopsis

```
const qa_int StatusCodes::TRANSMITTED
```

### Remarks

The message has been transmitted to the server.

This code has value 1. This code applies to the MMessageProperties::TRANSMISSION\_STATUS.

## TRANSMITTING variable

### Synopsis

```
const qa_int StatusCodes::TRANSMITTING
```

### Remarks

The message is in the process of being transmitted to the server.

This code has value 3. This code applies to the MMessageProperties::TRANSMISSION\_STATUS.

## UNRECEIVABLE variable

### Synopsis

```
const qa_int StatusCodes::UNRECEIVABLE
```

### Remarks

The message has been marked as unreceivable.

The message is either malformed, or there were too many failed attempts to deliver it. This code has value 50. This code applies to the MMessageProperties::STATUS.

## UNTRANSMITTED variable

### Synopsis

```
const qa_int StatusCodes::UNTRANSMITTED
```

### Remarks

The message has not been transmitted to the server.

This code has value 0. This code applies to the MMessageProperties::TRANSMISSION\_STATUS.

CHAPTER 14

# QAnywhere Java API Reference

## Contents

ianywhere.qanywhere.client package .....	504
ianywhere.qanywhere.ws package .....	602

### About this chapter

This chapter describes the QAnywhere Java API.

## ianywhere.qanywhere.client package

### Interface AcknowledgementMode

#### Synopsis

```
public ianywhere.qanywhere.client.AcknowledgementMode
```

#### Remarks

Indicates how messages should be acknowledged by QAnywhere client applications.

The implicit and explicit acknowledgement modes are assigned to a [Interface QAManager](#) instance using the [open method](#).

With implicit acknowledgement, messages are acknowledged as soon as they are received by a client application. With explicit acknowledgement, you must call one of the [Interface QAManager](#) acknowledgement methods. The server propagates all status changes from client to client.

#### See Also

[Interface QAManager](#)

[Interface QATransactionalManager](#)

[Interface QAManagerBase](#)

#### Members

All members of `ianywhere.qanywhere.client.AcknowledgementMode`, including all inherited members.

- ◆ [“EXPLICIT\\_ACKNOWLEDGEMENT variable” on page 504](#)
- ◆ [“IMPLICIT\\_ACKNOWLEDGEMENT variable” on page 505](#)
- ◆ [“TRANSACTIONAL variable” on page 505](#)

### EXPLICIT\_ACKNOWLEDGEMENT variable

#### Synopsis

```
final short ianywhere.qanywhere.client.AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT
```

#### Remarks

Indicates that received messages are acknowledged using one of the [Interface QAManager](#) acknowledge methods.

#### See Also

[Interface QAManager](#)

## IMPLICIT\_ACKNOWLEDGEMENT variable

### Synopsis

final short `ianywhere.qanywhere.client.AcknowledgementMode.IMPLICIT_ACKNOWLEDGEMENT`

### Remarks

Indicates that all messages are acknowledged as soon as they are received by a client application.

If you receive messages synchronously, messages are acknowledged as soon as the [getMessage method](#) returns. If you receive messages asynchronously, the message is acknowledged as soon as the event handling function returns.

## TRANSACTIONAL variable

### Synopsis

final short `ianywhere.qanywhere.client.AcknowledgementMode.TRANSACTIONAL`

### Remarks

This mode indicates that messages are only acknowledged as part of the on going transaction.

This mode is automatically assigned to [Interface QATransactionalManager](#) instances.

### See Also

[Interface QATransactionalManager](#)

## Interface MessageProperties

### Synopsis

public `ianywhere.qanywhere.client.MessageProperties`

### Remarks

Provides fields storing standard message property names.

The [Interface MessageProperties](#) class provides standard message property names. You can pass [Interface MessageProperties](#) fields to [Interface QAMessage](#) methods used to get and set message properties.

For example, assume you have the following [Interface QAMessage](#) instance: `QAMessage msg = mgr.createTextMessage();`

The following example gets the value corresponding to [MSG\\_TYPE variable](#) using the [getIntProperty method](#). The [Interface MessageType](#) enumeration maps the integer result to an appropriate message type.

```
int msg_type = t_msg.getIntProperty( MessageProperties.MSG_TYPE );
```

The following example shows the `onSystemMessage(QAMessage)` method, which is used to handle `QAnywhere` system messages.

```
private void onSystemMessage(QAMessage msg) {
    QATextMessage    t_msg;
    int              msg_type;
    String           network_adapters;
    String           network_names;
    String           network_info;

    t_msg = (QATextMessage)msg;
    if( t_msg != null ) {
        // Evaluate the message type.
        msg_type = (MessageType)t_msg.getIntProperty
( MessageProperties.MSG_TYPE );
        if( msg_type == MessageType.NETWORK_STATUS_NOTIFICATION ) {
            // Handle network status notification.
            network_info = "";
            network_adapters = t_msg.getStringProperty
( MessageProperties.ADAPTERS );
            if( network_adapters != null && network_adapters.length > 0 ) {
                network_info += network_adapters;
            }
            network_names = t_msg.getStringProperty
( MessageProperties.RAS_NAMES );

            //...
        }
    }
}
```

## Members

All members of `ianywhere.qanywhere.client.MessageProperties`, including all inherited members.

- ◆ “ADAPTER variable” on page 506
- ◆ “ADAPTERS variable” on page 507
- ◆ “DELIVERY\_COUNT variable” on page 507
- ◆ “IP variable” on page 507
- ◆ “MAC variable” on page 508
- ◆ “MSG\_TYPE variable” on page 508
- ◆ “NETWORK\_STATUS variable” on page 508
- ◆ “ORIGINATOR variable” on page 509
- ◆ “RAS variable” on page 509
- ◆ “RAS\_NAMES variable” on page 509
- ◆ “STATUS variable” on page 510
- ◆ “STATUS\_TIME variable” on page 510
- ◆ “TRANSMISSION\_STATUS variable” on page 510

## ADAPTER variable

### Synopsis

```
final String ianywhere.qanywhere.client.MessageProperties.ADAPTER
```

### Remarks

For "system" queue messages, the network adapter that is being used to connect to the QAnywhere server.

The value of this field is "ias\_Network.Adapter".

You can pass [ADAPTER variable](#) in the [getStringProperty method](#) to access the associated property. This property is read-only.

**See Also**

[Interface MessageProperties](#)

**ADAPTERS variable****Synopsis**

```
final String ianywhere.qanywhere.client.MessageProperties.ADAPTERS
```

**Remarks**

This property name refers to a delimited list of network adapters that can be used to connect to the QAnywhere server.

It is used for system queue messages.

You can pass [ADAPTERS variable](#) in the [getStringProperty method](#) to access the associated property. This property is read-only.

**See Also**

[Interface MessageProperties](#)

**DELIVERY\_COUNT variable****Synopsis**

```
final String ianywhere.qanywhere.client.MessageProperties.DELIVERY_COUNT
```

**Remarks**

This property name refers to the number of attempts that have been made so far to deliver the message.

**IP variable****Synopsis**

```
final String ianywhere.qanywhere.client.MessageProperties.IP
```

**Remarks**

For "system" queue messages, the IP address of the network adapter that is being used to connect to the QAnywhere server.

The value of this field is "ias\_Network.IP".

You can pass [IP variable](#) in the [getStringProperty method](#) to access the associated property. This property is read-only.

## See Also

[Interface MessageProperties](#)

## MAC variable

### Synopsis

```
final String ianywhere.qanywhere.client.MessageProperties.MAC
```

### Remarks

For "system" queue messages, the MAC address of the network adapter that is being used to connect to the QAnywhere server.

The value of this field is "ias\_Network.MAC".

You can pass [MAC variable](#) in the [getStringProperty method](#) to access the associated property. This property is read-only.

## See Also

[Interface MessageProperties](#)

## MSG\_TYPE variable

### Synopsis

```
final String ianywhere.qanywhere.client.MessageProperties.MSG_TYPE
```

### Remarks

This property name refers to [Interface MessageType](#) enumeration values associated with a QAnywhere message.

The value of this field is "ias\_MessageType".

You can pass [MSG\\_TYPE variable](#) in the [getIntProperty method](#) to access the associated property. This property is read-only.

## See Also

[Interface MessageProperties](#)

## NETWORK\_STATUS variable

### Synopsis

```
final String ianywhere.qanywhere.client.MessageProperties.NETWORK_STATUS
```

### Remarks

This property name refers to the state of the network connection.

The value is 1 if the network is accessible and 0 otherwise. The network status is used for system queue messages (for example, network status changes).

You can pass [NETWORK\\_STATUS variable](#) in the [getIntProperty method](#) to access the associated property. This property is read-only.

**See Also**

[Interface MessageProperties](#)

**ORIGINATOR variable****Synopsis**

```
final String ianywhere.qanywhere.client.MessageProperties.ORIGINATOR
```

**Remarks**

This property name refers to the message store ID of the originator of the message.

**RAS variable****Synopsis**

```
final String ianywhere.qanywhere.client.MessageProperties.RAS
```

**Remarks**

For "system" queue messages, the RAS entry name that is being used to connect to the QAnywhere server.

The value of this field is "ias\_Network.RAS".

You can pass [RAS variable](#) in the [getStringProperty method](#) to access the associated property. This property is read-only.

**See Also**

[Interface MessageProperties](#)

**RASNAMES variable****Synopsis**

```
final String ianywhere.qanywhere.client.MessageProperties.RASNAMES
```

**Remarks**

For "system" queue messages, a delimited list of RAS entry names that can be used to connect to the QAnywhere server.

The value of this field is "ias\_RASNames".

You can pass [RASNAMES variable](#) in the [getStringProperty method](#) to access the associated property. This property is read-only.

### See Also

[Interface MessageProperties](#)

## STATUS variable

### Synopsis

```
final String ianywhere.qanywhere.client.MessageProperties.STATUS
```

### Remarks

This property name refers to the current status of the message.

### See Also

[Interface StatusCodes](#)

## STATUS\_TIME variable

### Synopsis

```
final String ianywhere.qanywhere.client.MessageProperties.STATUS_TIME
```

### Remarks

This property name refers to the time at which the message assumed its current status.

If you pass `MessageProperties.StatusTime` to the [getProperty method](#), it returns a `java.util.Date` instance.

## TRANSMISSION\_STATUS variable

### Synopsis

```
final String ianywhere.qanywhere.client.MessageProperties.TRANSMISSION_STATUS
```

### Remarks

This property name refers to the current transmission status of the message.

### See Also

[Interface StatusCodes](#)

## Interface MessageStoreProperties

### Synopsis

```
public ianywhere.qanywhere.client.MessageStoreProperties
```

### Remarks

This class defines constant values for useful message store property names.

The [Interface MessageStoreProperties](#) class provides standard message property names. You can pass [Interface MessageProperties](#) fields to [Interface QAManagerBase](#) methods used to get and set pre-defined or custom message store properties.

## Members

All members of `ianywhere.qanywhere.client.MessageStoreProperties`, including all inherited members.

- ◆ [“MAX\\_DELIVERY\\_ATTEMPTS variable” on page 511](#)

## MAX\_DELIVERY\_ATTEMPTS variable

### Synopsis

```
final String ianywhere.qanywhere.client.MessageStoreProperties.MAX_DELIVERY_ATTEMPTS
```

### Remarks

This property name refers to the maximum number of times that a message can be received without being acknowledged before its status is set to [UNRECEIVABLE variable](#).

## Interface MessageType

### Synopsis

```
public ianywhere.qanywhere.client.MessageType
```

### Remarks

Defines constant values for the [MSG\\_TYPE variable](#) message property.

The following example shows the `onSystemMessage(QAMessage)` method, which is used to handle QAnywhere system messages. The message type is compared to [NETWORK\\_STATUS\\_NOTIFICATION variable](#).

```
private void onSystemMessage(QAMessage msg)
{
    QATextMessage    t_msg;
    int               msg_type;
    String            network_adapters;
    String            network_names;
    String            network_info;

    t_msg = (QATextMessage)msg;
    if( t_msg != null )
    {
        // Evaluate message type.
        msg_type = t_msg.getIntProperty( MessageProperties.MSG_TYPE );
        if( msg_type == MessageType.NETWORK_STATUS_NOTIFICATION )
        {
            // Handle network status notification.
        }
    }
}
```

## Members

All members of `ianywhere.qanywhere.client.MessageType`, including all inherited members.

- ◆ “[NETWORK\\_STATUS\\_NOTIFICATION variable](#)” on page 512
- ◆ “[PUSH\\_NOTIFICATION variable](#)” on page 512
- ◆ “[REGULAR variable](#)” on page 512

## NETWORK\_STATUS\_NOTIFICATION variable

### Synopsis

```
final int ianywhere.qanywhere.client.MessageType.NETWORK_STATUS_NOTIFICATION
```

### Remarks

Identifies a QAnywhere system message used to notify QAnywhere client applications of network status changes.

Network status changes apply to the device receiving the system message. Use the [ADAPTER variable](#), `MessageProperties.NETWORK`, and [NETWORK\\_STATUS variable](#) fields to identify new network status information.

## PUSH\_NOTIFICATION variable

### Synopsis

```
final int ianywhere.qanywhere.client.MessageType.PUSH_NOTIFICATION
```

### Remarks

Identifies a QAnywhere system message used to notify QAnywhere client applications of push notifications.

If you use the on-demand QAnywhere Agent policy, a typical response is to call the [triggerSendReceive method](#) to receive messages waiting with the central message server.

## REGULAR variable

### Synopsis

```
final int ianywhere.qanywhere.client.MessageType.REGULAR
```

### Remarks

If no message type property exists, the message type is assumed to be `REGULAR`.

This type of message is not treated specially by the message system.

## Interface PropertyType

### Synopsis

public **ianywhere.qanywhere.client.PropertyType**

### Remarks

[Interface QAMessage](#) property type enumeration, corresponding naturally to the Java types.

### Members

All members of `ianywhere.qanywhere.client.PropertyType`, including all inherited members.

- ◆ [“PROPERTY\\_TYPE\\_BOOLEAN variable” on page 513](#)
- ◆ [“PROPERTY\\_TYPE\\_BYTE variable” on page 513](#)
- ◆ [“PROPERTY\\_TYPE\\_DOUBLE variable” on page 513](#)
- ◆ [“PROPERTY\\_TYPE\\_FLOAT variable” on page 514](#)
- ◆ [“PROPERTY\\_TYPE\\_INT variable” on page 514](#)
- ◆ [“PROPERTY\\_TYPE\\_LONG variable” on page 514](#)
- ◆ [“PROPERTY\\_TYPE\\_SHORT variable” on page 514](#)
- ◆ [“PROPERTY\\_TYPE\\_STRING variable” on page 514](#)
- ◆ [“PROPERTY\\_TYPE\\_UNKNOWN variable” on page 514](#)

## PROPERTY\_TYPE\_BOOLEAN variable

### Synopsis

final short **ianywhere.qanywhere.client.PropertyType.PROPERTY\_TYPE\_BOOLEAN**

### Remarks

Indicates a boolean property.

## PROPERTY\_TYPE\_BYTE variable

### Synopsis

final short **ianywhere.qanywhere.client.PropertyType.PROPERTY\_TYPE\_BYTE**

### Remarks

Indicates a signed byte property.

## PROPERTY\_TYPE\_DOUBLE variable

### Synopsis

final short **ianywhere.qanywhere.client.PropertyType.PROPERTY\_TYPE\_DOUBLE**

### Remarks

Indicates a double property.

### **PROPERTY\_TYPE\_FLOAT variable**

#### **Synopsis**

final short `ianywhere.qanywhere.client.PropertyType.PROPERTY_TYPE_FLOAT`

#### **Remarks**

Indicates a float property.

### **PROPERTY\_TYPE\_INT variable**

#### **Synopsis**

final short `ianywhere.qanywhere.client.PropertyType.PROPERTY_TYPE_INT`

#### **Remarks**

Indicates an int property.

### **PROPERTY\_TYPE\_LONG variable**

#### **Synopsis**

final short `ianywhere.qanywhere.client.PropertyType.PROPERTY_TYPE_LONG`

#### **Remarks**

Indicates an long property.

### **PROPERTY\_TYPE\_SHORT variable**

#### **Synopsis**

final short `ianywhere.qanywhere.client.PropertyType.PROPERTY_TYPE_SHORT`

#### **Remarks**

Indicates a short property.

### **PROPERTY\_TYPE\_STRING variable**

#### **Synopsis**

final short `ianywhere.qanywhere.client.PropertyType.PROPERTY_TYPE_STRING`

#### **Remarks**

Indicates a String property.

### **PROPERTY\_TYPE\_UNKNOWN variable**

#### **Synopsis**

final short `ianywhere.qanywhere.client.PropertyType.PROPERTY_TYPE_UNKNOWN`

**Remarks**

Indicates an unknown property type, usually because the property is unknown.

**Interface QABinaryMessage****Synopsis**

```
public ianywhere.qanywhere.client.QABinaryMessage
```

**Base classes**

◆ [“Interface QAMessage” on page 570](#)

**Remarks**

A [Interface QABinaryMessage](#) object is used to send a message containing a stream of uninterpreted bytes.

[Interface QABinaryMessage](#) inherits from the [Interface QAMessage](#) class and adds a bytes message body. [Interface QABinaryMessage](#) provides a variety of functions to read from and write to the bytes message body.

When the message is first created, the body of the message is in write-only mode. After a message has been sent, the client that sent it can retain and modify it without affecting the message that has been sent. The same message object can be sent multiple times.

When a message is received, the provider has called [reset method](#) so that the message body is in read-only mode and reading of values starts from the beginning of the message body.

The following example uses the [writeString method](#) to write the string "Q" followed by the string "Anywhere" to a [Interface QABinaryMessage](#) instance's message body.

```
// Create a binary message instance.
QABinaryMessage binary_message;
binary_message = qa_manager.createBinaryMessage();

// Set optional message properties.
binary_message.setReplyToAddress("my-queue-name");

// Write to the message body.
binary_message.writeString("Q");
binary_message.writeString("Anywhere");

// Put the message in the local database, ready for sending.
try {
    qa_manager.putMessage("store-id\\queue-name", binary_message);
}
catch ( QAMessageException e ) {
    handleError();
}
```

*Note:* On the receiving end, the first [readString method](#) invocation returns "Q" and the next [readString method](#) invocation returns "Anywhere".

The message is sent by the QAnywhere Agent.

## getBodyLength method

### Synopsis

long `ianywhere.qanywhere.client.QABinaryMessage.getBodyLength()`  
throws `QAException`

### Throws

- ◆ Thrown if there is a problem retrieving the size of the message body.

### Remarks

Returns the size of the message body in bytes.

### See Also

[Interface QABinaryMessage](#)

### Returns

The size of the message body in bytes.

## readBinary method

### Synopsis

```
int ianywhere.qanywhere.client.QABinaryMessage.readBinary(  
    byte[] dest  
)  
throws QAException
```

### Parameters

- ◆ **dest** The byte array to hold the read bytes.

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads a specified number of bytes starting from the unread portion of a [Interface QABinaryMessage](#) instance body.

### See Also

[Interface QABinaryMessage](#)  
[writeBinary](#) method

### Returns

The number of bytes read from the message body.

## [readBinary](#) method

### Synopsis

```
int iAnywhere.qanywhere.client.QABinaryMessage.readBinary(  
    byte[] dest,  
    int length  
)  
throws QAException
```

### Parameters

- ◆ **dest** The byte array to hold the read bytes.
- ◆ **length** The maximum number of bytes to read.

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads a specified number of bytes starting from the unread portion of a [Interface QABinaryMessage](#) instance body.

### See Also

[Interface QABinaryMessage](#)  
[writeBinary](#) method

**Returns**

The number of bytes read from the message body.

**readBoolean method****Synopsis**

boolean `ianywhere.qanywhere.client.QABinaryMessage.readBoolean()`  
throws **QAException**

**Throws**

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

**Remarks**

Reads a boolean value starting from the unread portion of the [Interface QABinaryMessage](#) instance's message body.

**See Also**

[Interface QABinaryMessage](#)  
[writeBoolean method](#)

**Returns**

The boolean value read from the message body.

**readByte method****Synopsis**

byte `ianywhere.qanywhere.client.QABinaryMessage.readByte()`  
throws **QAException**

**Throws**

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

**Remarks**

Reads a signed byte value starting from the unread portion of a [Interface QABinaryMessage](#) message body.

**See Also**

[Interface QABinaryMessage](#)  
[writeByte method](#)

**Returns**

The signed byte value read from the message body.

## readChar method

### Synopsis

char **ianywhere.qanywhere.client.QABinaryMessage.readChar()**  
throws **QAException**

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads a char value starting from the unread portion of a [Interface QABinaryMessage](#) message body.

### See Also

[Interface QABinaryMessage](#)

[writeChar method](#)

### Returns

The character value read from the message body.

## readDouble method

### Synopsis

double **ianywhere.qanywhere.client.QABinaryMessage.readDouble()**  
throws **QAException**

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads a double value starting from the unread portion of a [Interface QABinaryMessage](#) message body.

### See Also

[Interface QABinaryMessage](#)

[writeDouble method](#)

### Returns

The double value read from the message body.

## readFloat method

### Synopsis

float `ianywhere.qanywhere.client.QABinaryMessage.readFloat()`  
throws `QAException`

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads a float value starting from the unread portion of a [Interface QABinaryMessage](#) message body.

### See Also

[Interface QABinaryMessage](#)

[writeFloat method](#)

### Returns

The float value read from the message body.

## readInt method

### Synopsis

int `ianywhere.qanywhere.client.QABinaryMessage.readInt()`  
throws `QAException`

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads an integer value starting from the unread portion of a [Interface QABinaryMessage](#) message body.

### See Also

[Interface QABinaryMessage](#)

[writeInt method](#)

### Returns

The int value read from the message body.

## readLong method

### Synopsis

long `iAnywhere.qanywhere.client.QABinaryMessage.readLong()`  
throws `QAException`

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads a long value starting from the unread portion of a [Interface QABinaryMessage](#) message body.

### See Also

[Interface QABinaryMessage](#)

[writeLong method](#)

### Returns

The long value read from the message body.

## readShort method

### Synopsis

short `iAnywhere.qanywhere.client.QABinaryMessage.readShort()`  
throws `QAException`

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads a short value starting from the unread portion of a [Interface QABinaryMessage](#) message body.

### See Also

[Interface QABinaryMessage](#)

[writeShort method](#)

### Returns

The short value read from the message body.

## readString method

### Synopsis

String **ianywhere.qanywhere.client.QABinaryMessage.readString()**  
throws **QAException**

### Throws

- ◆ Thrown if there was a conversion error reading the value or if there is no more input.

### Remarks

Reads a string value starting from the unread portion of a [Interface QABinaryMessage](#) message body.

### See Also

[Interface QABinaryMessage](#)

[writeString method](#)

### Returns

The string value read from the message body.

## reset method

### Synopsis

void **ianywhere.qanywhere.client.QABinaryMessage.reset()**  
throws **QAException**

### Throws

- ◆ Thrown if there is a problem resetting the message.

### Remarks

Resets a message so that the reading of values starts from the beginning of the message body.

The reset method also puts the [Interface QABinaryMessage](#) message body in read-only mode.

### See Also

[Interface QABinaryMessage](#)

## writeBinary method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeBinary(  
    byte[] val  
)  
throws QAException
```

### Parameters

- ◆ **val** The byte array value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the byte array to the message body.

### Remarks

Appends a byte array value to the [Interface QABinaryMessage](#) instance's message body.

### See Also

[Interface QABinaryMessage](#)

[readBinary](#) method

### writeBinary method

#### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeBinary(  
    byte[] val,  
    int len  
)  
throws QAException
```

### Parameters

- ◆ **val** The byte array value to write to the message body.
- ◆ **len** The number of bytes to write.

### Throws

- ◆ Thrown if there is a problem appending the byte array to the message body.

### Remarks

Appends a byte array value to the [Interface QABinaryMessage](#) instance's message body.

### See Also

[Interface QABinaryMessage](#)

[readBinary](#) method

### writeBinary method

#### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeBinary(  
    byte[] val,
```

```
    int offset,  
    int len  
    )  
    throws QAEException
```

### Parameters

- ◆ **val** The byte array value to write to the message body.
- ◆ **offset** The offset within the byte array to begin writing.
- ◆ **len** The number of bytes to write.

### Throws

- ◆ Thrown if there is a problem appending the byte array to the message body.

### Remarks

Appends a byte array value to the [Interface QABinaryMessage](#) instance's message body.

### See Also

[Interface QABinaryMessage](#)  
[readBinary method](#)

## writeBoolean method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeBoolean(  
    boolean val  
    )  
    throws QAEException
```

### Parameters

- ◆ **val** The boolean value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the boolean value to the message body.

### Remarks

Appends a boolean value to the [Interface QABinaryMessage](#) instance's message body.

The boolean is represented as a one byte value. True is represented as 1; false is represented as 0.

### See Also

[Interface QABinaryMessage](#)  
[readBoolean method](#)

## writeByte method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeByte(  
    byte val  
)  
throws QAException
```

### Parameters

- ◆ **val** The signed byte value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the signed byte value to the message body.

### Remarks

Appends a signed byte value to the [Interface QABinaryMessage](#) instance's message body.

The signed byte is represented as a one byte value.

### See Also

[Interface QABinaryMessage](#)

[readByte method](#)

## writeChar method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeChar(  
    char val  
)  
throws QAException
```

### Parameters

- ◆ **val** The char value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the char value to the message body.

### Remarks

Appends a char value to the [Interface QABinaryMessage](#) instance's message body.

The char is represented as a two byte value and the high order byte is appended first.

### See Also

[Interface QABinaryMessage](#)

[readChar method](#)

## writeDouble method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeDouble(  
    double val  
)  
throws QAException
```

### Parameters

- ◆ **val** the double value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the double value to the message body.

### Remarks

Appends a double value to the [Interface QABinaryMessage](#) instance's message body.

The double is converted to a representative 8-byte long and higher order bytes are appended first.

### See Also

[Interface QABinaryMessage](#)  
[readDouble method](#)

## writeFloat method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeFloat(  
    float val  
)  
throws QAException
```

### Parameters

- ◆ **val** The float value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the float value to the message body.

### Remarks

Appends a float value to the [Interface QABinaryMessage](#) instance's message body.

The float is converted to a representative 4-byte integer and the higher order bytes are appended first.

### See Also

[Interface QABinaryMessage](#)  
[readFloat method](#)

## writeInt method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeInt(  
    int val  
)  
throws QAException
```

### Parameters

- ◆ **val** The int value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the integer value to the message body.

### Remarks

Appends an integer value to the [Interface QABinaryMessage](#) instance's message body.

The integer parameter is represented as a 4 byte value and higher order bytes are appended first.

### See Also

[Interface QABinaryMessage](#)  
[readInt method](#)

## writeLong method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeLong(  
    long val  
)  
throws QAException
```

### Parameters

- ◆ **val** The long value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the long value to the message body.

### Remarks

Appends a long value to the [Interface QABinaryMessage](#) instance's message body.

The long parameter is represented using 8-bytes value and higher order bytes are appended first.

### See Also

[Interface QABinaryMessage](#)  
[readLong method](#)

## writeShort method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeShort(  
    short val  
)  
throws QAException
```

### Parameters

- ◆ **val** The short value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the short value to the message body.

### Remarks

Appends a short value to the [Interface QABinaryMessage](#) instance's message body.

The short parameter is represented as a two byte value and the higher order byte is appended first.

### See Also

[Interface QABinaryMessage](#)  
[readShort method](#)

## writeString method

### Synopsis

```
void ianywhere.qanywhere.client.QABinaryMessage.writeString(  
    String val  
)  
throws QAException
```

### Parameters

- ◆ **val** The string value to write to the message body.

### Throws

- ◆ Thrown if there is a problem appending the string value to the message body.

### Remarks

Appends a string value to the [Interface QABinaryMessage](#) instance's message body.

*Note:* The receiving application needs to invoke [readString method](#) for each WriteString invocation. *Note:* The UTF-8 representation of the string to be written can be at most 32767 bytes.

### See Also

[Interface QABinaryMessage](#)

[readString method](#)

## Class QAException

### Synopsis

```
public ianywhere.qanywhere.client.QAException
```

### Remarks

Encapsulates QAnywhere client application exceptions.

You can use the [Class QAException](#) class to catch QAnywhere exceptions.

```
try
{
    _qaManager = QAManagerFactory.getInstance().CreateQAManager();
    _qaManager.open( AcknowledgementMode.EXPLICIT_ACKNOWLEDGEMENT );
    _qaManager.start();
}
catch( QAException e )
{
    // Handle exception.
    System.err.println("Error code: " + e.getErrorCode() );
    System.err.println("Error message: " + e.getMessage() );
}
}
```

### **COMMON\_ALREADY\_OPEN\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_ALREADY_OPEN_ERROR`

#### **Remarks**

The [Interface QAManager](#) is already open.

### **COMMON\_GETQUEUEDEPTH\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_GETQUEUEDEPTH_ERROR`

#### **Remarks**

Error getting the queue depth.

### **COMMON\_GETQUEUEDEPTH\_ERROR\_INVALID\_ARG variable**

#### **Synopsis**

final int  
`ianywhere.qanywhere.client.QAException.COMMON_GETQUEUEDEPTH_ERROR_INVALID_ARG`

#### **Remarks**

Cannot use [getQueueDepth method](#) on a given destination when filter is ALL.

### **COMMON\_GETQUEUEDEPTH\_ERROR\_NO\_STORE\_ID variable**

#### **Synopsis**

final int  
`ianywhere.qanywhere.client.QAException.COMMON_GETQUEUEDEPTH_ERROR_NO_STORE_ID`

#### **Remarks**

Cannot use [getQueueDepth method](#) when the message store ID has not been set.

### **COMMON\_GET\_INIT\_FILE\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_GET_INIT_FILE_ERROR`

#### **Remarks**

Unable to access the client properties file.

### **COMMON\_INIT\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_INIT_ERROR`

#### **Remarks**

Initialization error.

### **COMMON\_INIT\_THREAD\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_INIT_THREAD_ERROR`

#### **Remarks**

Error initializing the background thread.

### **COMMON\_INVALID\_PROPERTY variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_INVALID_PROPERTY`

#### **Remarks**

There is an invalid property in the client properties file.

### **COMMON\_MSG\_ACKNOWLEDGE\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_MSG_ACKNOWLEDGE_ERROR`

#### **Remarks**

Error acknowledging the message.

### **COMMON\_MSG\_CANCEL\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_MSG_CANCEL_ERROR`

**Remarks**

Error cancelling message.

**COMMON\_MSG\_CANCEL\_ERROR\_SENT variable****Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_MSG_CANCEL_ERROR_SENT
```

**Remarks**

Error cancelling message.

Cannot cancel a message that has already been sent.

**COMMON\_MSG\_NOT\_WRITEABLE\_ERROR variable****Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_MSG_NOT_WRITEABLE_ERROR
```

**Remarks**

You cannot write to a message that is in read-only mode.

**COMMON\_MSG\_RETRIEVE\_ERROR variable****Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_MSG_RETRIEVE_ERROR
```

**Remarks**

Error retrieving a message from the client message store.

**COMMON\_MSG\_STORE\_ERROR variable****Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_MSG_STORE_ERROR
```

**Remarks**

Error storing a message in the client message store.

**COMMON\_MSG\_STORE\_NOT\_INITIALIZED variable****Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_MSG_STORE_NOT_INITIALIZED
```

**Remarks**

The message store has not been initialized for messaging.

### **COMMON\_MSG\_STORE\_TOO\_LARGE variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_MSG_STORE_TOO_LARGE`

#### **Remarks**

The message store is too large relative to the free disk space on the device.

### **COMMON\_NOT\_OPEN\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_NOT_OPEN_ERROR`

#### **Remarks**

The [Interface QAManager](#) is not open.

### **COMMON\_NO\_DEST\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_NO_DEST_ERROR`

#### **Remarks**

No destination.

### **COMMON\_NO\_IMPLEMENTATION variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_NO_IMPLEMENTATION`

#### **Remarks**

The method is not implemented.

### **COMMON\_OPEN\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_OPEN_ERROR`

#### **Remarks**

Error opening a connection to the message store.

### **COMMON\_OPEN\_LOG\_FILE\_ERROR variable**

#### **Synopsis**

final int `ianywhere.qanywhere.client.QAException.COMMON_OPEN_LOG_FILE_ERROR`

**Remarks**

Error opening the log file.

**COMMON\_SELECTOR\_SYNTAX\_ERROR** variable**Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_SELECTOR_SYNTAX_ERROR
```

**Remarks**

The given selector has a syntax error.

**COMMON\_TERMINATE\_ERROR** variable**Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_TERMINATE_ERROR
```

**Remarks**

Termination error.

**COMMON\_UNEXPECTED\_EOM\_ERROR** variable**Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_UNEXPECTED_EOM_ERROR
```

**Remarks**

Unexpected end of message reached.

**COMMON\_UNREPRESENTABLE\_TIMESTAMP** variable**Synopsis**

```
final int ianywhere.qanywhere.client.QAException.COMMON_UNREPRESENTABLE_TIMESTAMP
```

**Remarks**

The timestamp is outside of the acceptable range.

**QAException** method**Synopsis**

```
ianywhere.qanywhere.client.QAException.QAException(  
    String message,  
    int errorCode  
)
```

**Parameters**

- ◆ **message** The text description of the exception.
- ◆ **errorCode** The error code.

### Remarks

Creates a [Class QAException](#) instance with the provided error code and error message text.

### QA\_NO\_ERROR variable

### Synopsis

```
final int ianywhere.qanywhere.client.QAException.QA_NO_ERROR
```

### Remarks

No error.

### getErrorCode method

### Synopsis

```
int ianywhere.qanywhere.client.QAException.getErrorCode()
```

### Remarks

Returns the error code of the last exception.

### Returns

The error code of the last exception.

## Interface QAManager

### Synopsis

```
public ianywhere.qanywhere.client.QAManager
```

### Base classes

- ◆ [“Interface QAManagerBase” on page 540](#)

### Remarks

[Interface QAManager](#) derives from [Interface QAManagerBase](#).

It manages non-transactional QAnywhere messaging operations.

For a detailed description of derived behavior, see [Interface QAManagerBase](#).

The [Interface QAManager](#) instance can be configured for implicit or explicit acknowledgement, as defined in the [Interface AcknowledgementMode](#) class. To acknowledge messages as part of a transaction, use [Interface QATransactionalManager](#).

Use the [Class QAManagerFactory](#) class to create [Interface QAManager](#) and [Interface QATransactionalManager](#) objects.

### Members

All members of `ianywhere.qanywhere.client.QAManager`, including all inherited members.

## acknowledge method

### Synopsis

```
void iAnywhere.qAnywhere.client.QAManager.acknowledge(  
    QAMessage msg  
)  
throws QAEException
```

### Parameters

- ◆ **msg** The message to acknowledge.

### Throws

- ◆ Thrown if there is a problem acknowledging the message.

### Remarks

Acknowledges that the client application successfully received a QAnywhere message.

*Note:* When a [Interface QAMessage](#) is acknowledged, its status property changes to [RECEIVED variable](#). It can then be deleted using the default delete rule.

### See Also

[Interface QAManager](#)

[acknowledgeUntil method](#)

[acknowledgeAll method](#)

## acknowledgeAll method

### Synopsis

```
void iAnywhere.qAnywhere.client.QAManager.acknowledgeAll()  
throws QAEException
```

### Throws

- ◆ Thrown if there is a problem acknowledging the messages.

### Remarks

Acknowledges that the client application successfully received QAnywhere messages.

All unacknowledged messages are acknowledged.

*Note:* When a [Interface QAMessage](#) is acknowledged, its status property changes to [RECEIVED variable](#). It can then be deleted using the default delete rule.

**See Also**

[Interface QAManager](#)  
[acknowledge method](#)  
[acknowledgeUntil method](#)

**acknowledgeUntil method****Synopsis**

```
void ianywhere.qanywhere.client.QAManager.acknowledgeUntil(  
    QAMessage msg  
)  
throws QAException
```

**Parameters**

- ◆ **msg** The last message to acknowledge. All earlier unacknowledged messages are also acknowledged.

**Throws**

- ◆ Thrown if there is a problem acknowledging the messages.

**Remarks**

Acknowledges the given [Interface QAMessage](#) instance and all unacknowledged messages received before the given message.

*Note:* When a [Interface QAMessage](#) is acknowledged, its status property changes to [RECEIVED variable](#). It can then be deleted using the default delete rule.

**See Also**

[Interface QAManager](#)  
[acknowledge method](#)  
[acknowledgeAll method](#)

**open method****Synopsis**

```
void ianywhere.qanywhere.client.QAManager.open(  
    short mode  
)  
throws QAException
```

**Parameters**

- ◆ **mode** The acknowledgement mode, one of “[EXPLICIT\\_ACKNOWLEDGEMENT variable](#)” on page 504 or “[IMPLICIT\\_ACKNOWLEDGEMENT variable](#)” on page 505.

### Throws

- ◆ Thrown if there is a problem opening the [“Interface QAManager” on page 536](#) instance.

### Remarks

Opens the [Interface QAManager](#) with the given [Interface AcknowledgementMode](#) value.

The [open method](#) must be the first method called after creating a [Interface QAManager](#).

### See Also

[Interface AcknowledgementMode](#)

[Interface QAManager](#)

## recover method

### Synopsis

```
void ianywhere.qanywhere.client.QAManager.recover()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem recovering.

### Remarks

Forces all unacknowledged messages into a state of unreceived.

These messages must be received again using [getMessage method](#).

### See Also

[Interface QAManager](#)

## Interface QAManagerBase

### Synopsis

```
public ianywhere.qanywhere.client.QAManagerBase
```

### Derived classes

- ◆ [“Interface QAManager” on page 536](#)
- ◆ [“Interface QATransactionalManager” on page 594](#)

### Remarks

This class acts as a base class for [Interface QATransactionalManager](#) and [Interface QAManager](#), which manage transactional and non-transactional messaging, respectively.

Use the [start method](#) to allow a [Interface QAManagerBase](#) instance to listen for messages. An instance of [Interface QAManagerBase](#) must be used only on the thread that created it.

You can use instances of this class to create and manage QAnywhere messages. Use the [createBinaryMessage method](#) and [createTextMessage method](#) to create appropriate [Interface QAMessage](#) instances. [Interface QAMessage](#) instances provide a variety of methods to set message content and properties. To send QAnywhere messages, use the [putMessage method](#) to place the addressed message in the local message store queue. The message is transmitted by the QAnywhere Agent based on its transmission policies or when you call [triggerSendReceive method](#).

[Interface QAManagerBase](#) also provides methods to set and get message store properties.

## Members

## browseMessages method

### Synopsis

```
java.util.Enumeration ianywhere.qanywhere.client.QAManagerBase.browseMessages()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem browsing the messages.

### Remarks

Browses all available messages in the message store.

The messages are just being browsed, so they cannot be acknowledged.

Use [getMessage method](#) to receive messages so that they can be acknowledged.

### See Also

[browseMessagesByQueue method](#)

[browseMessagesByID method](#)

### Returns

An enumerator over the available messages.

## browseMessagesByID method

### Synopsis

```
java.util.Enumeration ianywhere.qanywhere.client.QAManagerBase.browseMessagesByID(  
    String id  
)  
throws QAException
```

### Parameters

- ◆ **id** The message ID of the message.

**Throws**

- ◆ Thrown if there is a problem browsing the messages.

**Remarks**

Browse the message with the given message ID.

The message is just being browsed, so it cannot be acknowledged. Use [getMessage method](#) to receive messages so that they can be acknowledged.

**See Also**

[browseMessagesByQueue method](#)

[browseMessages method](#)

**Returns**

An enumerator containing 0 or 1 messages.

**[browseMessagesByQueue method](#)****Synopsis**

```
java.util.Enumeration ianywhere.qanywhere.client.QAManagerBase.browseMessagesByQueue(  
    String address  
)  
throws QAException
```

**Parameters**

- ◆ **address** The address of the messages.

**Throws**

- ◆ Thrown if there is a problem browsing the messages.

**Remarks**

Browses the available messages waiting that have been sent to the given address.

The messages are just being browsed, so they cannot be acknowledged.

Use [getMessage method](#) to receive messages so they can be acknowledged.

**See Also**

[browseMessagesByID method](#)

[browseMessages method](#)

**Returns**

An enumerator over the available messages.

## **browseMessagesBySelector method**

### **Synopsis**

```
java.util.Enumeration ianywhere.qanywhere.client.QAManagerBase.browseMessagesBySelector(  
    String selector  
)  
throws QAException
```

### **Parameters**

- ◆ **selector** The selector.

### **Throws**

- ◆ Thrown if there is a problem browsing the messages.

### **Remarks**

Browse messages queued in the message store that satisfy the given selector.

The message is just being browsed, so it cannot be acknowledged. Use [getMessage method](#) to receive messages so that they can be acknowledged.

### **See Also**

[browseMessagesByQueue method](#)

[browseMessages method](#)

[browseMessagesByID method](#)

### **Returns**

An enumerator over the available messages.

## **cancelMessage method**

### **Synopsis**

```
boolean ianywhere.qanywhere.client.QAManagerBase.cancelMessage(  
    String id  
)  
throws QAException
```

### **Parameters**

- ◆ **id** The message ID of the message to cancel.

### **Throws**

- ◆ Thrown if there is a problem cancelling the message.

### **Remarks**

Cancels the message with the given message ID.

Puts a message into a cancelled state before it is transmitted.

With the default delete rules of the QAnywhere Agent, cancelled messages are eventually deleted from the message store.

Fails if the message is already in a final state, or if the message has been transmitted to the central messaging server.

## close method

### Synopsis

void **ianywhere.qanywhere.client.QAManagerBase.close()**  
throws **QAException**

### Throws

- ◆ Thrown if there is a problem closing the “[Interface QAManagerBase](#)” on page 540 instance.

### Remarks

Closes the connection to the QAnywhere message system and releases any resources used by the [Interface QAManagerBase](#).

Additional calls to [close method](#) following the first are ignored. Any subsequent calls to a [Interface QAManagerBase](#) method, other than [close method](#), result in a [Class QAException](#). You must create and open a new [Interface QAManagerBase](#) instance in this case.

## createBinaryMessage method

### Synopsis

QABinaryMessage **ianywhere.qanywhere.client.QAManagerBase.createBinaryMessage()**  
throws **QAException**

### Throws

- ◆ Thrown if there is a problem creating the message.

### Remarks

Creates a [Interface QABinaryMessage](#) object.

A [Interface QABinaryMessage](#) object is used to send a message containing a message body of uninterpreted bytes.

### See Also

[Interface QABinaryMessage](#)

### Returns

A new [Interface QABinaryMessage](#) instance.

## createTextMessage method

### Synopsis

`QATextMessage ianywhere.qanywhere.client.QAManagerBase.createTextMessage()`  
throws **QAException**

### Throws

- ◆ Thrown if there is a problem creating the message.

### Remarks

Creates a [Interface QATextMessage](#) object.

A [Interface QATextMessage](#) object is used to send a message containing a string message body.

### See Also

[Interface QATextMessage](#)

### Returns

A new [Interface QATextMessage](#) instance.

## getBooleanStoreProperty method

### Synopsis

`boolean ianywhere.qanywhere.client.QAManagerBase.getBooleanStoreProperty(  
String name  
)`  
throws **QAException**

### Parameters

- ◆ **name** The pre-defined or custom property name.

### Throws

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a boolean value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

### See Also

[Interface MessageStoreProperties](#)

### Returns

The boolean property value.

## getBytesStoreProperty method

### Synopsis

```
byte ianywhere.qanywhere.client.QAManagerBase.getBytesStoreProperty(  
    String name  
)  
throws QAException
```

### Parameters

- ◆ **name** The pre-defined or custom property name.

### Throws

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a signed byte value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

### See Also

[Interface MessageStoreProperties](#)

### Returns

The signed byte property value.

## getDoubleStoreProperty method

### Synopsis

```
double ianywhere.qanywhere.client.QAManagerBase.getDoubleStoreProperty(  
    String name  
)  
throws QAException
```

### Parameters

- ◆ **name** the pre-defined or custom property name.

### Throws

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a double value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

## See Also

[Interface MessageStoreProperties](#)

## Returns

The double property value.

## getFloatStoreProperty method

### Synopsis

```
float ianywhere.qanywhere.client.QAManagerBase.getFloatStoreProperty(  
    String name  
)  
throws QAException
```

### Parameters

◆ **name** The pre-defined or custom property name.

### Throws

◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a float value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

## See Also

[Interface MessageStoreProperties](#)

## Returns

The float property value.

## getIntStoreProperty method

### Synopsis

```
int ianywhere.qanywhere.client.QAManagerBase.getIntStoreProperty(  
    String name  
)  
throws QAException
```

### Parameters

◆ **name** The pre-defined or custom property name.

**Throws**

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

**Remarks**

Gets a int value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

**See Also**

[Interface MessageStoreProperties](#)

**Returns**

The integer property value.

**getLongStoreProperty method****Synopsis**

```
long ianywhere.qanywhere.client.QAManagerBase.getLongStoreProperty(  
    String name  
)  
throws QAException
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.

**Throws**

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

**Remarks**

Gets a long value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

**See Also**

[Interface MessageStoreProperties](#)

**Returns**

The long property value.

## getMessage method

### Synopsis

```
QAMessage ianywhere.qanywhere.client.QAManagerBase.getMessage(  
    String address  
)  
throws QAException
```

### Parameters

- ◆ **address** This address specifies the queue name used by the QAnywhere client to receive messages.

### Throws

- ◆ Thrown if there is a problem getting the message.

### Remarks

Returns the next available [Interface QAMessage](#) sent to the specified address.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If there is no message available, this call blocks indefinitely until a message is available. Use this method to receive messages synchronously.

### Returns

The next [Interface QAMessage](#), or null if no message is available.

## getMessageBySelector method

### Synopsis

```
QAMessage ianywhere.qanywhere.client.QAManagerBase.getMessageBySelector(  
    String address,  
    String selector  
)  
throws QAException
```

### Parameters

- ◆ **address** This address specifies the queue name used by the QAnywhere client to receive messages.
- ◆ **selector** The selector.

### Throws

- ◆ Thrown if there is a problem getting the message.

### Remarks

Returns the next available [Interface QAMessage](#) sent to the specified address that satisfies the given selector.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If there is no message available, this call blocks indefinitely until a message is available.

Use this method to receive messages synchronously.

### Returns

The next [Interface QAMessage](#), or null if no message is available.

## getMessageBySelectorNoWait method

### Synopsis

```
QAMessage ianywhere.qanywhere.client.QAManagerBase.getMessageBySelectorNoWait(  
    String address,  
    String selector  
)  
throws QAException
```

### Parameters

- ◆ **address** This address specifies the queue name used by the QAnywhere client to receive messages.
- ◆ **selector** The selector.

### Throws

- ◆ Thrown if there is a problem getting the message.

### Remarks

Returns the next available [Interface QAMessage](#) sent to the given address that satisfies the given selector.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method returns immediately.

Use this method to receive messages synchronously.

### Returns

The next available message or null there is no available message.

## getMessageBySelectorTimeout method

### Synopsis

```
QAMessage ianywhere.qanywhere.client.QAManagerBase.getMessageBySelectorTimeout(  
    String address,  
    String selector,  
    long timeout  
)  
throws QAException
```

### Parameters

- ◆ **address** This address specifies the queue name used by the QAnywhere client to receive messages.

- ◆ **selector** The selector.
- ◆ **timeout** The time to wait, in milliseconds, for a message to become available.

### Throws

- ◆ Thrown if there is a problem getting the message.

### Remarks

Returns the next available [Interface QAMessage](#) sent to the given address that satisfies the given selector.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method waits for the specified timeout and then returns.

Use this method to receive messages synchronously.

### Returns

The next [Interface QAMessage](#), or null if no message is available.

## getMessageListener method

### Synopsis

```
QAMessageListener i anywhere.q anywhere.client.QAManagerBase.getMessageListener(  
    String address  
)  
throws QAException
```

### Parameters

- ◆ **address** A local queue name used to receive messages, or system.

### Throws

- ◆ Thrown if there is a problem getting the listener.

### Remarks

Returns the [Interface QAMessageListener](#) associated with the specified queue.

If there is no [Interface QAMessageListener](#) associated with the specified queue, returns null.

### Returns

The listener.

## getMessageNoWait method

### Synopsis

```
QAMessage i anywhere.q anywhere.client.QAManagerBase.getMessageNoWait(  
    String address
```

)  
throws **QAException**

### Parameters

◆ **address** This address specifies the queue name used by the QAnywhere client to receive messages.

### Throws

◆ Thrown if there is a problem getting the message.

### Remarks

Returns the next available [Interface QAMessage](#) sent to the given address.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method returns immediately.

Use this method to receive messages synchronously.

### Returns

The next available message or null there is no available message.

## [getMessageTimeout method](#)

### Synopsis

```
QAMessage ianywhere.qanywhere.client.QAManagerBase.getMessageTimeout(  
    String address,  
    long timeout  
)  
throws QAException
```

### Parameters

◆ **address** This address specifies the queue name used by the QAnywhere client to receive messages.

◆ **timeout** The time to wait, in milliseconds, for a message to become available.

### Throws

◆ Thrown if there is a problem getting the message.

### Remarks

Returns the next available [Interface QAMessage](#) sent to the given address.

The address parameter specifies a local queue name. The address can be in the form 'store-id\queue-name' or 'queue-name'. If no message is available, this method waits for the specified timeout and then returns.

Use this method to receive messages synchronously.

### Returns

the next [Interface QAMessage](#), or null if no message is available.

## getMode method

### Synopsis

short `iAnywhere.qanywhere.client.QAManagerBase.getMode()`  
throws `QAException`

### Throws

- ◆ Thrown if there is a problem retrieving the “[Interface QAManager](#)” on page 536 acknowledgement mode

### Remarks

Returns the [Interface QAManager](#) acknowledgement mode for received messages.

For a list of return values, see [Interface AcknowledgementMode](#).

`EXPLICIT_ACKNOWLEDGEMENT` variable and `IMPLICIT_ACKNOWLEDGEMENT` variable apply to [Interface QAManager](#) instances. `TRANSACTIONAL` variable is the mode for [Interface QATransactionalManager](#) instances.

### Returns

The [Interface QAManager](#) acknowledgement mode for received messages.

## getQueueDepth method

### Synopsis

int `iAnywhere.qanywhere.client.QAManagerBase.getQueueDepth(`  
short *filter*  
`)`  
throws `QAException`

### Parameters

- ◆ **filter** A filter indicating incoming messages, outgoing messages, or all messages.

### Throws

- ◆ Thrown if there was an error.

### Remarks

Returns the total depth of all queues, based on a given filter.

The depth of the queue is the number of messages that have not been received (for example, using the [getMessage method](#)).

See [Interface QueueDepthFilter](#) for a list of possible filter values.

### Returns

The number of messages in all queues for the given filter.

## getQueueDepth method

### Synopsis

```
int ianywhere.qanywhere.client.QAManagerBase.getQueueDepth(  
    String queue,  
    short filter  
)  
throws QAException
```

### Parameters

- ◆ **queue** A filter indicating incoming messages, outgoing messages, or all messages.
- ◆ **filter** The queue name.

### Throws

- ◆ Thrown if there was an error.

### Remarks

Returns the depth of a queue, based on a given filter.

The depth of the queue is the number of messages that have not been received (for example, using the [getMessage method](#)).

See [Interface QueueDepthFilter](#) for a list of possible filter values.

### Returns

the number of messages.

## getShortStoreProperty method

### Synopsis

```
short ianywhere.qanywhere.client.QAManagerBase.getShortStoreProperty(  
    String name  
)  
throws QAException
```

### Parameters

- ◆ **name** The pre-defined or custom property name.

### Throws

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a short value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

## See Also

[Interface MessageStoreProperties](#)

## Returns

The short property value.

## getStoreProperty method

### Synopsis

```
Object ianywhere.qanywhere.client.QAManagerBase.getStoreProperty(  
    String name  
)  
throws QAException
```

### Parameters

◆ **name** The pre-defined or custom property name.

### Throws

◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets an Object representing a message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

## See Also

[Interface MessageStoreProperties](#)

## Returns

The property value.

## getStorePropertyNames method

### Synopsis

```
java.util.Enumeration ianywhere.qanywhere.client.QAManagerBase.getStorePropertyNames()  
throws QAException
```

### Throws

◆ Thrown if there is a problem retrieving the enumerator.

### Remarks

Gets an enumerator over the message store property names.

**Returns**

An enumerator over the message store property names.

**getStringStoreProperty method****Synopsis**

```
String ianywhere.qanywhere.client.QAManagerBase.getStringStoreProperty(  
    String name  
)  
throws QAException
```

**Parameters**

◆ **name** The pre-defined or custom property name.

**Throws**

◆ Thrown if there is a problem retrieving the string value.

**Remarks**

Gets a string value for a pre-defined or custom message store property.

You can use this method to access pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

**See Also**

[Interface MessageStoreProperties](#)

**Returns**

The string property value or null if the property does not exist.

**putMessage method****Synopsis**

```
void ianywhere.qanywhere.client.QAManagerBase.putMessage(  
    String address,  
    QAMessage msg  
)  
throws QAException
```

**Parameters**

◆ **address** The address of the message specifying the destination queue name.

◆ **msg** The message to put in the local message store for transmission.

**Throws**

◆ Thrown if there is a problem putting the message.

## Remarks

Prepares a message to send to another QAnywhere client.

This method inserts a message and a destination address into your local message store. The time of message transmission depends on QAnywhere Agent transmission policies.

The address takes the form 'id\queue-name', where 'id' is the destination message store id and 'queue-name' identifies a queue that is used by the destination QAnywhere client to listen for or receive messages.

## See Also

[putMessageTimeToLive method](#)

## putMessageTimeToLive method

### Synopsis

```
void i anywhere.q anywhere.client.QAManagerBase.putMessageTimeToLive(  
    String address,  
    QAMessage msg,  
    long ttl  
)  
throws QAException
```

### Parameters

- ◆ **address** The address of the message specifying the destination queue name.
- ◆ **msg** The message to put.
- ◆ **ttl** The delay, in milliseconds, before the message expires if it has not been delivered. A value of 0 indicates the message does not expire.

### Throws

- ◆ Thrown if there is a problem putting the message.

## Remarks

Prepares a message to send to another QAnywhere client.

This method inserts a message and a destination address into your local message store. The time of message transmission depends on QAnywhere Agent transmission policies. However, if the next message transmission time exceeds the given time-to-live value, the message expires.

The address takes the form 'id\queue-name', where 'id' is the destination message store id and 'queue-name' identifies a queue that is used by the destination QAnywhere client to listen for or receive messages.

## setBooleanStoreProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAManagerBase.setBooleanStoreProperty(  
    String name,  
    boolean value  
)  
throws QAException
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The boolean property value.

### Throws

- ◆ Thrown if there is a problem setting the message store property.

### Remarks

Sets a pre-defined or custom message store property to a boolean value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

### See Also

[Interface MessageStoreProperties](#)

## setByteStoreProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAManagerBase.setByteStoreProperty(  
    String name,  
    byte value  
)  
throws QAException
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The sbyte property value.

### Throws

- ◆ Thrown if there is a problem setting the message store property.

### Remarks

Sets a pre-defined or custom message store property to a sbyte value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

### See Also

[Interface MessageStoreProperties](#)

## setDoubleStoreProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAManagerBase.setDoubleStoreProperty(  
    String name,  
    double value  
)  
throws QAException
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The double property value.

### Throws

- ◆ Thrown if there is a problem setting the message store property.

### Remarks

Sets a pre-defined or custom message store property to a double value.

You can use this method to set pre-defined or user-defined client. store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

### See Also

[Interface MessageStoreProperties](#)

## setFloatStoreProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAManagerBase.setFloatStoreProperty(  
    String name,  
    float value  
)  
throws QAException
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The float property value.

**Throws**

- ◆ Thrown if there is a problem setting the message store property.

**Remarks**

Sets a pre-defined or custom message store property to a float value.

You can use this method to set pre-defined or user-defined client store properties. For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

**See Also**

[Interface MessageStoreProperties](#)

**setIntStoreProperty method****Synopsis**

```
void ianywhere.qanywhere.client.QAManagerBase.setIntStoreProperty(  
    String name,  
    int value  
)  
throws QAException
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The int property value.

**Throws**

- ◆ Thrown if there is a problem setting the message store property.

**Remarks**

Sets a pre-defined or custom message store property to a int value.

You can use this method to set pre-defined or user-defined client store properties. For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

**See Also**

[Interface MessageStoreProperties](#)

**setLongStoreProperty method****Synopsis**

```
void ianywhere.qanywhere.client.QAManagerBase.setLongStoreProperty(  
    String name,  
    long value
```

)  
throws **QAException**

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The long property value.

### Throws

- ◆ Thrown if there is a problem setting the message store property.

### Remarks

Sets a pre-defined or custom message store property to a long value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

### See Also

[Interface MessageStoreProperties](#)

## setMessageListener method

### Synopsis

```
void ianywhere.qanywhere.client.QAManagerBase.setMessageListener(  
    String address,  
    QAMessageListener listener  
)  
throws QAException
```

### Parameters

- ◆ **address** The address of a local queue name used to receive messages, or system to listen for QAnywhere system messages.
- ◆ **listener** The listener.

### Throws

- ◆ Thrown if there is a problem registering the “[Interface QAMessageListener](#)” on page 588 object, such as because there is already a listener object assigned to the given queue.

### Remarks

Registers a [Interface QAMessageListener](#) object to receive QAnywhere messages asynchronously.

The address parameter specifies a local queue name used to receive the message. You can only have one listener object assigned to a given queue. If you want to listen for QAnywhere system messages, including push notifications and network status changes, specify "system" as the queue name.

Use this method to receive messages asynchronously.

## setMessageListenerBySelector method

### Synopsis

```
void ianywhere.qanywhere.client.QAManagerBase.setMessageListenerBySelector(  
    String address,  
    String selector,  
    QAMessageListener listener  
)  
throws QAException
```

### Parameters

- ◆ **address** The address of a local queue name used to receive messages, or system to listen for QAnywhere system messages.
- ◆ **selector** The selector to be used to filter the messages to be received.
- ◆ **listener** The listener.

### Throws

- ◆ Thrown if there is a problem registering the [“Interface QAMessageListener” on page 588](#) object, such as because there is already a listener object assigned to the given queue.

### Remarks

Registers a [Interface QAMessageListener](#) object to receive QAnywhere messages asynchronously, with a message selector.

The address parameter specifies a local queue name used to receive the message. You can only have one listener object assigned to a given queue. The selector parameter specifies a selector to be used to filter the messages to be received on the given address. If you want to listen for QAnywhere system messages, including push notifications and network status changes, specify "system" as the queue name.

Use this method to receive messages asynchronously.

## setShortStoreProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAManagerBase.setShortStoreProperty(  
    String name,  
    short value  
)  
throws QAException
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The short property value.

### Throws

- ◆ Thrown if there is a problem setting the message store property.

### Remarks

Sets a pre-defined or custom message store property to a short value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

### See Also

[Interface MessageStoreProperties](#)

## setStoreProperty method

### Synopsis

```
void i anywhere.q anywhere.client.QAManagerBase.setStoreProperty(  
    String name,  
    Object value  
)  
throws QAException
```

### Parameters

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the message store property to the value.

### Remarks

Sets a pre-defined or custom message store property to a System.Object value.

The property type must correspond to one of the acceptable primitive types, or String. You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

### See Also

[Interface MessageStoreProperties](#)

## setStringStoreProperty method

### Synopsis

```
void i anywhere.q anywhere.client.QAManagerBase.setStringStoreProperty(  
    String name,  
    String value  
)  
throws QAException
```

**Parameters**

- ◆ **name** The pre-defined or custom property name.
- ◆ **value** The String property value.

**Throws**

- ◆ Thrown if there is a problem setting the message store property to a string value.

**Remarks**

Sets a pre-defined or custom message store property to a String value.

You can use this method to set pre-defined or user-defined client store properties.

For a list of pre-defined properties, see [Interface MessageStoreProperties](#).

**See Also**

[Interface MessageStoreProperties](#)

**start method****Synopsis**

```
void ianywhere.qanywhere.client.QAManagerBase.start()  
throws QAException
```

**Throws**

- ◆ Thrown if there is a problem starting the “[Interface QAManagerBase](#)” on page 540 instance.

**Remarks**

Starts the [Interface QAManagerBase](#) for receiving incoming messages.

Any calls to this method beyond the first without an intervening [stop method](#) call are ignored.

**See Also**

[stop method](#)

**stop method****Synopsis**

```
void ianywhere.qanywhere.client.QAManagerBase.stop()  
throws QAException
```

**Throws**

- ◆ Thrown if there is a problem stopping the “[Interface QAManagerBase](#)” on page 540 instance.

## Remarks

Halts the QAManagerBase's reception of incoming messages.

The messages are not lost. They just are not received until the manager is started again. Any calls to [stop method](#) beyond the first without an intervening [start method](#) call are ignored.

## See Also

[start method](#)

## triggerSendReceive method

### Synopsis

```
void ianywhere.qanywhere.client.QAManagerBase.triggerSendReceive()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem triggering the send/receive.

## Remarks

Causes a synchronization with the QAnywhere message server, uploading any messages addressed to other clients, and downloading any messages addressed to the local client.

A call to this method results in immediate message synchronization between a QAnywhere Agent and the central messaging server. A manual [triggerSendReceive method](#) call results in immediate message transmission, independent of the QAnywhere Agent transmission policies.

QAnywhere Agent transmission policies determine how message transmission occurs. For example, message transmission can occur automatically at regular intervals, when your client receives a push notification, or when you call the [putMessage method](#) to send a message.

## See Also

[putMessage method](#)

## Class QAManagerFactory

### Synopsis

```
public ianywhere.qanywhere.client.QAManagerFactory
```

### Remarks

This class acts as a factory class for creating [Interface QATransactionalManager](#) and [Interface QAManager](#) objects.

You can only have one instance of [Class QAManagerFactory](#).

## Members

All members of `ianywhere.qanywhere.client.QAManagerFactory`, including all inherited members.

- ◆ [“createQAManager method” on page 567](#)
- ◆ [“createQAManager method” on page 567](#)
- ◆ [“createQAManager method” on page 568](#)
- ◆ [“createQATransactionalManager method” on page 568](#)
- ◆ [“createQATransactionalManager method” on page 569](#)
- ◆ [“createQATransactionalManager method” on page 570](#)
- ◆ [“getInstance method” on page 570](#)

## createQAManager method

### Synopsis

```
abstract QAManager ianywhere.qanywhere.client.QAManagerFactory.createQAManager(  
    String iniFile  
)  
throws QAException
```

### Parameters

- ◆ **iniFile** A properties file for configuring the [“Interface QAManager” on page 536](#) instance, or null to create the [“Interface QAManager” on page 536](#) instance using default properties.

### Throws

- ◆ Thrown if there is a problem creating the manager.

### Remarks

Returns a new [Interface QAManager](#) instance with the specified properties.

If the `iniFile` parameter is null, the [Interface QAManager](#) is created using default properties. You can use the [Interface QAManagerBase](#) set property methods to set [Interface QAManager](#) properties programmatically after you create the instance.

### See Also

[Interface QAManager](#)

### Returns

A new [Interface QAManager](#) instance.

## createQAManager method

### Synopsis

```
abstract QAManager ianywhere.qanywhere.client.QAManagerFactory.createQAManager(  
    java.util.Hashtable properties
```

)  
throws **QAException**

#### Parameters

- ◆ **properties** A hashtable for configuring the “[Interface QAManager](#)” on page 536 instance.

#### Throws

- ◆ Thrown if there is a problem creating the manager.

#### Remarks

Returns a new [Interface QAManager](#) instance with the specified properties as a Hashtable.

#### See Also

[Interface QAManager](#)

#### Returns

A new [Interface QAManager](#) instance.

### **createQAManager method**

#### Synopsis

```
abstract QAManager ianywhere.qanywhere.client.QAManagerFactory.createQAManager()  
throws QAException
```

#### Throws

- ◆ Thrown if there is a problem creating the manager.

#### Remarks

Returns a new [Interface QAManager](#) instance with default properties.

#### See Also

[Interface QAManager](#)

#### Returns

A new [Interface QAManager](#) instance.

### **createQATransactionalManager method**

#### Synopsis

```
abstract QATransactionalManager  
ianywhere.qanywhere.client.QAManagerFactory.createQATransactionalManager(  
String iniFile
```

)  
throws **QAException**

### Parameters

- ◆ **iniFile** A properties file for configuring the “[Interface QATransactionalManager](#)” on page 594 instance.

### Throws

- ◆ Thrown if there is a problem creating the manager.

### Remarks

Returns a new [Interface QATransactionalManager](#) instance with the specified properties.

If the iniFile parameter is null, the [Interface QATransactionalManager](#) is created using default properties. You can use the [Interface QAManagerBase](#) set property methods to set [Interface QATransactionalManager](#) properties programmatically after you create the instance.

### See Also

[Interface QATransactionalManager](#)

### Returns

The configured [Interface QATransactionalManager](#).

## createQATransactionalManager method

### Synopsis

```
abstract QATransactionalManager  
ianywhere.qanywhere.client.QAManagerFactory.createQATransactionalManager(  
    java.util.Hashtable properties  
)  
throws QAException
```

### Parameters

- ◆ **properties** A hashtable for configuring the “[Interface QATransactionalManager](#)” on page 594 instance.

### Throws

- ◆ Thrown if there is a problem creating the manager.

### Remarks

Returns a new [Interface QAManager](#) instance with the specified properties.

### See Also

[Interface QATransactionalManager](#)

## Returns

The configured [Interface QATransactionalManager](#).

## createQATransactionalManager method

### Synopsis

```
abstract QATransactionalManager  
iAnywhere.qAnywhere.client.QAManagerFactory.createQATransactionalManager()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem creating the manager.

### Remarks

Returns a new [Interface QAManager](#) instance with default properties.

### See Also

[Interface QATransactionalManager](#)

## Returns

A new [Interface QATransactionalManager](#).

## getInstance method

### Synopsis

```
QAManagerFactory iAnywhere.qAnywhere.client.QAManagerFactory.getInstance()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem creating the manager factory.

### Remarks

Returns the singleton [Class QAManagerFactory](#) instance.

## Returns

The singleton [Class QAManagerFactory](#) instance

## Interface QAMessage

### Synopsis

```
public iAnywhere.qAnywhere.client.QAMessage
```

## Derived classes

- ◆ “[Interface QABinaryMessage](#)” on page 515
- ◆ “[Interface QATextMessage](#)” on page 589

## Remarks

[Interface QAMessage](#) provides an interface to set message properties and header fields.

The derived classes [Interface QABinaryMessage](#) and [Interface QATextMessage](#) provide specialized functions to read and write to the message body. You can use [Interface QAMessage](#) functions to set predefined or custom message properties. For a list of pre-defined property names, see the [Interface MessageProperties](#).

## Members

All members of `ianywhere.qanywhere.client.QAMessage`, including all inherited members.

## DEFAULT\_PRIORITY variable

### Synopsis

```
final int ianywhere.qanywhere.client.QAMessage.DEFAULT_PRIORITY
```

### Remarks

The default message priority.

## DEFAULT\_TIME\_TO\_LIVE variable

### Synopsis

```
final long ianywhere.qanywhere.client.QAMessage.DEFAULT_TIME_TO_LIVE
```

### Remarks

The default time-to-live value.

## clearProperties method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.clearProperties()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem clearing the message properties.

### Remarks

Clear all the properties of the message.

## getAddress method

### Synopsis

```
String ianywhere.qanywhere.client.QAMessage.getAddress()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem retrieving the destination address.

### Remarks

Returns the destination address for the [Interface QAMessage](#) instance.

When a message is sent, this field is ignored. After completion of a send operation, the field holds the destination address specified in [putMessage method](#).

**Returns**

The destination address for the [Interface QAMessage](#) instance.

**getBooleanProperty method****Synopsis**

```
boolean ianywhere.qanywhere.client.QAMessage.getBooleanProperty(  
    String name  
)  
throws QAException
```

**Parameters**

◆ **name** The property name.

**Throws**

◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

**Remarks**

Gets a boolean message property.

**Returns**

The property value.

**See Also**

[Interface MessageProperties](#)

**getBytesProperty method****Synopsis**

```
byte ianywhere.qanywhere.client.QAMessage.getBytesProperty(  
    String name  
)  
throws QAException
```

**Parameters**

◆ **name** The property name.

**Throws**

◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a signed byte message property.

### Returns

The property value.

### See Also

[Interface MessageProperties](#)

## getDoubleProperty method

### Synopsis

```
double ianywhere.qanywhere.client.QAMessage.getDoubleProperty(  
    String name  
)  
throws QAException
```

### Parameters

◆ **name** The property name.

### Throws

◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a double message property.

### Returns

The property value.

### See Also

[Interface MessageProperties](#)

## getExpiration method

### Synopsis

```
java.util.Date ianywhere.qanywhere.client.QAMessage.getExpiration()  
throws QAException
```

### Throws

◆ Thrown if there is a problem getting the expiration.

### Remarks

Returns the message's expiration value, or null if the message does not expire or has not yet been sent.

When a message is sent, the expiration is left unassigned. After the send operation completes, it holds the expiration time of the message.

This is a read-only property because the expiration time of a message is set by adding the time-to-live argument of [putMessageTimeToLive method](#) to the current time.

### Returns

The message's expiration value, or null if the message does not expire or has not yet been sent.

## getFloatProperty method

### Synopsis

```
float ianywhere.qanywhere.client.QAMessage.getFloatProperty(  
    String name  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.

### Throws

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a float message property.

### Returns

The property value.

### See Also

[Interface MessageProperties](#)

## getInReplyToID method

### Synopsis

```
String ianywhere.qanywhere.client.QAMessage.getInReplyToID()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem getting the message ID of the message to which this message is a reply.

### Remarks

Returns the message ID of the message to which this message is a reply.

## Returns

The message ID of the message to which this message is a reply, or null if this message is not a reply.

## getIntProperty method

### Synopsis

```
int ianywhere.qanywhere.client.QAMessage.getIntProperty(  
    String name  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.

### Throws

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets an int message property.

## Returns

The property value.

## See Also

[Interface MessageProperties](#)

## getLongProperty method

### Synopsis

```
long ianywhere.qanywhere.client.QAMessage.getLongProperty(  
    String name  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.

### Throws

- ◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a long message property.

**Returns**

The property value.

**See Also**

[Interface MessageProperties](#)

**getMessageID method****Synopsis**

String **ianywhere.qanywhere.client.QAMessage.getMessageID()**  
throws **QAException**

**Throws**

- ◆ Thrown if there is a problem getting the message ID.

**Remarks**

Returns the globally unique message ID of the message.

This property is null until a message is put.

When a message is sent using [putMessage method](#) the message ID is null and can be ignored. When the send method returns, it contains an assigned value.

**Returns**

The message ID of the message, or null if the message has not yet been put.

**getPriority method****Synopsis**

int **ianywhere.qanywhere.client.QAMessage.getPriority()**  
throws **QAException**

**Throws**

- ◆ Thrown if there is a problem getting the message priority.

**Remarks**

Returns the priority of the message (ranging from 0 to 9).

**Returns**

The priority of the message.

## getProperty method

### Synopsis

```
Object ianywhere.qanywhere.client.QAMessage.getProperty(  
    String name  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.

### Throws

- ◆ Thrown if there is a conversion error getting the property value.

### Remarks

Gets a message property.

### Returns

The property value, or null if the property does not exist.

## getPropertyNames method

### Synopsis

```
java.util.Enumeration ianywhere.qanywhere.client.QAMessage.getPropertyNames()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem getting the enumerator over the property names of the message.

### Remarks

Gets an enumerator over the property names of the message.

### Returns

An enumerator over the message property names.

## getPropertyType method

### Synopsis

```
short ianywhere.qanywhere.client.QAMessage.getPropertyType(  
    String name  
)  
throws QAException
```

**Parameters**

- ◆ **name** The property name.

**Throws**

- ◆ Thrown if there is a problem retrieving the property type.

**Remarks**

Returns the property type of the given property.

**See Also**

[Interface PropertyType](#)

**Returns**

The property type.

**getRedelivered method****Synopsis**

```
boolean ianywhere.qanywhere.client.QAMessage.getRedelivered()  
throws QAException
```

**Throws**

- ◆ Thrown if there is a problem retrieving the redelivered status.

**Remarks**

Indicates whether the message has been previously received but not acknowledged.

Redelivered is set by a receiving [Interface QAManager](#) when it detects that a message being received was received before. For example, an application receives a message using a [Interface QAManager](#) opened with [EXPLICIT\\_ACKNOWLEDGEMENT variable](#), and shuts down without acknowledging the message. When the application starts again and receives the same message, the message will be marked as redelivered.

**Returns**

True if the message has been previously received but not acknowledged.

**getReplyToAddress method****Synopsis**

```
String ianywhere.qanywhere.client.QAMessage.getReplyToAddress()  
throws QAException
```

**Throws**

- ◆ Thrown if there is a problem retrieving the reply-to address.

### Remarks

Returns the reply-to address of this message.

### Returns

The reply-to address of this message, or null if it does not exist.

## getShortProperty method

### Synopsis

```
short ianywhere.qanywhere.client.QAMessage.getShortProperty(  
    String name  
)  
throws QAException
```

### Parameters

◆ **name** the property name.

### Throws

◆ Thrown if there is a conversion error getting the property value or if the property does not exist.

### Remarks

Gets a short message property.

### Returns

The property value.

### See Also

[Interface MessageProperties](#)

## getStringProperty method

### Synopsis

```
String ianywhere.qanywhere.client.QAMessage.getStringProperty(  
    String name  
)  
throws QAException
```

### Parameters

◆ **name** The property name.

### Throws

◆ Thrown if there is a problem retrieving the message property.

**Remarks**

Gets a String message property.

**Returns**

The property value, or null if the property does not exist.

**See Also**

[Interface MessageProperties](#)

**getTimestamp method****Synopsis**

```
java.util.Date ianywhere.qanywhere.client.QAMessage.getTimestamp()  
throws QAException
```

**Throws**

- ◆ Thrown if there is a problem retrieving the message timestamp.

**Remarks**

Returns the message timestamp, which is the time the message was created.

**Returns**

The message timestamp.

**propertyExists method****Synopsis**

```
boolean ianywhere.qanywhere.client.QAMessage.propertyExists(  
    String name  
)  
throws QAException
```

**Parameters**

- ◆ **name** The property name

**Throws**

- ◆ Thrown if there is a problem checking if the property has been set.

**Remarks**

Indicates whether the given property has been set for this message.

## Returns

True if the property exists.

## setAddress method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setAddress(  
    String dest  
)  
throws QAEException
```

### Parameters

◆ **dest** The destination address.

### Throws

◆ Thrown if there is a problem setting the message destination address.

### Remarks

Sets the message destination address.

## setBooleanProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setBooleanProperty(  
    String name,  
    boolean value  
)  
throws QAEException
```

### Parameters

◆ **name** The property name.

◆ **value** The property value.

### Throws

◆ Thrown if there is a problem setting the property.

### Remarks

Sets a boolean property.

### See Also

[Interface MessageProperties](#)

## setByteProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setByteProperty(  
    String name,  
    byte value  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the property.

### Remarks

Sets a signed byte property.

### See Also

[Interface MessageProperties](#)

## setDoubleProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setDoubleProperty(  
    String name,  
    double value  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the property.

### Remarks

Sets a double property.

### See Also

[Interface MessageProperties](#)

## setFloatProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setFloatProperty(  
    String name,  
    float value  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the property.

### Remarks

Sets a float property.

### See Also

[Interface MessageProperties](#)

## setInReplyToID method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setInReplyToID(  
    String id  
)  
throws QAException
```

### Parameters

- ◆ **id** The ID of the message this message is in reply to.

### Throws

- ◆ Thrown if there is a problem setting the in reply to ID.

### Remarks

Sets the in reply to ID, which identifies the message this message is a reply to.

## setIntProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setIntProperty(  
    String name,  
    int value  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the property.

### Remarks

Sets an int property.

### See Also

[Interface MessageProperties](#)

## setLongProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setLongProperty(  
    String name,  
    long value  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the property.

### Remarks

Sets a long property.

### See Also

[Interface MessageProperties](#)

## setPriority method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setPriority(  
    int priority  
)  
throws QAException
```

### Parameters

- ◆ **priority** The priority of the message.

### Throws

- ◆ Thrown if there is a problem setting the priority.

### Remarks

Sets the priority of the message (ranging from 0 to 9).

## setProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setProperty(  
    String name,  
    Object value  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the property.

### Remarks

Sets a property.

The property type must correspond to one of the acceptable primitive types, or String.

### See Also

[Interface MessageProperties](#)

## setReplyToAddress method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setReplyToAddress(  
    String address  
)  
throws QAException
```

### Parameters

- ◆ **address** The reply-to address.

### Throws

- ◆ Thrown if there is a problem setting the reply-to address.

### Remarks

Sets the reply-to address.

## setShortProperty method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessage.setShortProperty(  
    String name,  
    short value  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the property.

### Remarks

Sets a short property.

### See Also

[Interface MessageProperties](#)

## setStringProperty method

### Synopsis

```
void i anywhere.q anywhere.client.QAMessage.setStringProperty(  
    String name,  
    String value  
)  
throws QAException
```

### Parameters

- ◆ **name** The property name.
- ◆ **value** The property value.

### Throws

- ◆ Thrown if there is a problem setting the property.

### Remarks

Sets a string property.

### See Also

[Interface MessageProperties](#)

## Interface QAMessageListener

### Synopsis

```
public i anywhere.q anywhere.client.QAMessageListener
```

### Remarks

To listen for messages, implement this interface and register your implementation by calling `QAManagerBase.setMessageListener(String, QAMessageListener)`.

### Members

All members of `i anywhere.q anywhere.client.QAMessageListener`, including all inherited members.

- ◆ [“onException method” on page 588](#)
- ◆ [“onMessage method” on page 589](#)

## onException method

### Synopsis

```
void i anywhere.q anywhere.client.QAMessageListener.onException(  
    QAException exception,  
    QAMessage message  
)
```

### Parameters

- ◆ **exception** The exception that occurred.
- ◆ **message** If the exception occurred after the message was passed to [“onMessage method” on page 589](#), the message that was processed. Otherwise, null.

### Remarks

This method is called whenever an exception occurs while listening for messages.

Note that this method cannot be used to automatically close the [Interface QAManagerBase](#) instance, as the [close method](#) blocks until all message listeners are finished processing.

## onMessage method

### Synopsis

```
void ianywhere.qanywhere.client.QAMessageListener.onMessage(  
    QAMessage message  
)
```

### Parameters

- ◆ **message** The message that was received.

### Remarks

This method is called whenever a message is received.

## Interface QATextMessage

### Synopsis

```
public ianywhere.qanywhere.client.QATextMessage
```

### Base classes

- ◆ [“Interface QAMessage” on page 570](#)

### Remarks

[Interface QATextMessage](#) inherits from the [Interface QAMessage](#) class and adds a text message body, and methods to read from and write to the text message body.

When the message is first created, the body of the message is in write-only mode. After a message has been sent, the client that sent it can retain and modify it without affecting the message that has been sent. The same message object can be sent multiple times.

When a message is received, the provider has called [reset method](#) so that the message body is in read-only mode and reading values starts from the beginning of the message body.

### Members

All members of `ianywhere.qanywhere.client.QATextMessage`, including all inherited members.

- ◆ “clearProperties method” on page 572
- ◆ “DEFAULT\_PRIORITY variable” on page 572

- ◆ “setText method” on page 592
- ◆ “writeText method” on page 593
- ◆ “writeText method” on page 593
- ◆ “writeText method” on page 593

## getText method

### Synopsis

String **ianywhere.qanywhere.client.QATextMessage.getText()**  
throws **QAException**

### Throws

- ◆ Thrown if there is a problem retrieving the message text.

### Remarks

Returns the message text.

If the message text exceeds the maximum size specified by the [Interface QAManager](#) `MAX_IN_MEMORY_MESSAGE_SIZE` property, this method returns null. In this case, use the [readText method](#) to read the text.

### Returns

The message text, or null .

## getTextLength method

### Synopsis

long **ianywhere.qanywhere.client.QATextMessage.getTextLength()**  
throws **QAException**

### Throws

- ◆ Thrown if there is a problem retrieving the length of the message.

### Remarks

Returns the length, in characters, of the message.

### Returns

The length in characters of the message.

## readText method

### Synopsis

String **ianywhere.qanywhere.client.QATextMessage.readText(  
int *maxLength*  
)**  
throws **QAException**

### Parameters

- ◆ **maxLength** The maximum number of characters to read.

### Throws

- ◆ Thrown if there is a problem retrieving the unread text.

### Remarks

Returns unread text from the message.

Any additional unread text must be read by subsequent calls to this method. Text is read from the beginning of any unread text.

### Returns

The text.

## reset method

### Synopsis

```
void ianywhere.qanywhere.client.QATextMessage.reset()  
throws QAException
```

### Throws

- ◆ Thrown if there is a problem resetting the text position of the message.

### Remarks

Resets the text position of the message to the beginning.

## setText method

### Synopsis

```
void ianywhere.qanywhere.client.QATextMessage.setText(  
    String value  
)  
throws QAException
```

### Parameters

- ◆ **value** The text to write to the message body.

### Throws

- ◆ Thrown if there is a problem overwriting the message text.

### Remarks

Overwrites the message text.

## writeText method

### Synopsis

```
void ianywhere.qanywhere.client.QATextMessage.writeText(  
    String value  
)  
throws QAException
```

### Parameters

- ◆ **value** The text to append.

### Throws

- ◆ Thrown if there is a problem appending the message text.

### Remarks

Appends text to the text of the message.

## writeText method

### Synopsis

```
void ianywhere.qanywhere.client.QATextMessage.writeText(  
    String value,  
    int length  
)  
throws QAException
```

### Parameters

- ◆ **value** The text to append.
- ◆ **length** The number of characters of text to append.

### Throws

- ◆ Thrown if there is a problem appending the message text.

### Remarks

Appends text to the text of the message.

## writeText method

### Synopsis

```
void ianywhere.qanywhere.client.QATextMessage.writeText(  
    String value,  
    int offset,  
    int length
```

)  
throws **QAException**

### Parameters

- ◆ **value** The text to append.
- ◆ **offset** The offset into value of the text to append.
- ◆ **length** The number of characters of text to append.

### Throws

- ◆ Thrown if there is a problem appending the message text.

### Remarks

Appends text to the text of the message.

## Interface **QATransactionalManager**

### Synopsis

```
public ianywhere.qanywhere.client.QATransactionalManager
```

### Base classes

- ◆ [“Interface QAManagerBase” on page 540](#)

### Remarks

The [Interface QATransactionalManager](#) class derives from [Interface QAManagerBase](#) and manages transactional QAnywhere messaging operations.

For a detailed description of derived behavior, see [Interface QAManagerBase](#).

[Interface QATransactionalManager](#) instances can only be used for transactional acknowledgement. Use the [commit method](#) to commit all [putMessage method](#) and [getMessage method](#) invocations.

### Members

All members of `ianywhere.qanywhere.client.QATransactionalManager`, including all inherited members.

- ◆ [“browseMessages method” on page 542](#)
- ◆ [“browseMessagesByID method” on page 542](#)
- ◆ [“browseMessagesByQueue method” on page 543](#)
- ◆ [“browseMessagesBySelector method” on page 544](#)
- ◆ [“cancelMessage method” on page 544](#)
- ◆ [“close method” on page 545](#)
- ◆ [“commit method” on page 595](#)
- ◆ [“createBinaryMessage method” on page 545](#)
- ◆ [“createTextMessage method” on page 546](#)
- ◆ [“getBooleanStoreProperty method” on page 546](#)

- ◆ “getByteStoreProperty method” on page 547
- ◆ “getDoubleStoreProperty method” on page 547
- ◆ “getFloatStoreProperty method” on page 548
- ◆ “getIntStoreProperty method” on page 548
- ◆ “getLongStoreProperty method” on page 549
- ◆ “getMessage method” on page 550
- ◆ “getMessageBySelector method” on page 550
- ◆ “getMessageBySelectorNoWait method” on page 551
- ◆ “getMessageBySelectorTimeout method” on page 551
- ◆ “getMessageListener method” on page 552
- ◆ “getMessageNoWait method” on page 552
- ◆ “getMessageTimeout method” on page 553
- ◆ “getMode method” on page 554
- ◆ “getQueueDepth method” on page 554
- ◆ “getQueueDepth method” on page 555
- ◆ “getShortStoreProperty method” on page 555
- ◆ “getStoreProperty method” on page 556
- ◆ “getStorePropertyNames method” on page 556
- ◆ “getStringStoreProperty method” on page 557
- ◆ “open method” on page 596
- ◆ “putMessage method” on page 557
- ◆ “putMessageTimeToLive method” on page 558
- ◆ “rollback method” on page 596
- ◆ “setBooleanStoreProperty method” on page 559
- ◆ “setByteStoreProperty method” on page 559
- ◆ “setDoubleStoreProperty method” on page 560
- ◆ “setFloatStoreProperty method” on page 560
- ◆ “setIntStoreProperty method” on page 561
- ◆ “setLongStoreProperty method” on page 561
- ◆ “setMessageListener method” on page 562
- ◆ “setMessageListenerBySelector method” on page 563
- ◆ “setShortStoreProperty method” on page 563
- ◆ “setStoreProperty method” on page 564
- ◆ “setStringStoreProperty method” on page 564
- ◆ “start method” on page 565
- ◆ “stop method” on page 565
- ◆ “triggerSendReceive method” on page 566

## commit method

### Synopsis

void `ianywhere.qanywhere.client.QATransactionalManager.commit()`  
throws `QAException`

### Throws

- ◆ Thrown if there is a problem committing.

### Remarks

Commits the current transaction and begins a new transaction.

This method commits all [putMessage method](#) and [getMessage method](#) invocations.

*Note:* The first transaction begins with the call to [open method](#).

### open method

#### Synopsis

```
void ianywhere.qanywhere.client.QATransactionalManager.open()  
throws QAException
```

#### Throws

- ◆ Thrown if there is a problem opening the manager.

#### Remarks

Opens a [Interface QATransactionalManager](#) instance.

This method must be the first method called after creating a manager.

#### See Also

[Interface QATransactionalManager](#)

### rollback method

#### Synopsis

```
void ianywhere.qanywhere.client.QATransactionalManager.rollback()  
throws QAException
```

#### Throws

- ◆ Thrown if there is a problem rolling back.

#### Remarks

Rolls back the current transaction and begins a new transaction.

This method rolls back all uncommitted [putMessage method](#) and [getMessage method](#) invocations.

#### See Also

[Interface QATransactionalManager](#)

## Interface QueueDepthFilter

### Synopsis

public **ianywhere.qanywhere.client.QueueDepthFilter**

### Remarks

Provides queue depth filter values for [getQueueDepth method](#) and [getQueueDepth method](#).

### Members

All members of `ianywhere.qanywhere.client.QueueDepthFilter`, including all inherited members.

- ◆ [“ALL variable” on page 597](#)
- ◆ [“INCOMING variable” on page 597](#)
- ◆ [“OUTGOING variable” on page 597](#)

## ALL variable

### Synopsis

final short **ianywhere.qanywhere.client.QueueDepthFilter.ALL**

### Remarks

This filter specifies both incoming and outgoing messages.

System messages and expired messages are not included in any queue depth counts.

## INCOMING variable

### Synopsis

final short **ianywhere.qanywhere.client.QueueDepthFilter.INCOMING**

### Remarks

This filter specifies only incoming messages.

An incoming message is defined as a message whose originator is different than the agent ID of the message store.

## OUTGOING variable

### Synopsis

final short **ianywhere.qanywhere.client.QueueDepthFilter.OUTGOING**

### Remarks

This filter specifies only outgoing messages.

An outgoing message is defined as a message whose originator is the agent ID of the message store, and whose destination is not the agent ID of the message store.

## Interface StatusCodes

### Synopsis

```
public ianywhere.qanywhere.client.StatusCodes
```

### Remarks

This interface defines a set of codes for the status of a message.

### Members

All members of `ianywhere.qanywhere.client.StatusCodes`, including all inherited members.

- ◆ [“CANCELLED variable” on page 598](#)
- ◆ [“EXPIRED variable” on page 598](#)
- ◆ [“FINAL variable” on page 599](#)
- ◆ [“LOCAL variable” on page 599](#)
- ◆ [“PENDING variable” on page 599](#)
- ◆ [“RECEIVED variable” on page 599](#)
- ◆ [“RECEIVING variable” on page 600](#)
- ◆ [“TRANSMITTED variable” on page 600](#)
- ◆ [“TRANSMITTING variable” on page 600](#)
- ◆ [“UNRECEIVABLE variable” on page 600](#)
- ◆ [“UNTRANSMITTED variable” on page 601](#)

## CANCELLED variable

### Synopsis

```
final int ianywhere.qanywhere.client.StatusCodes.CANCELLED
```

### Remarks

The message has been cancelled.

This code applies to the [STATUS variable](#).

## EXPIRED variable

### Synopsis

```
final int ianywhere.qanywhere.client.StatusCodes.EXPIRED
```

### Remarks

The message has expired; the message was not received before its expiration time had passed.

This code applies to the [STATUS variable](#).

## **FINAL variable**

### **Synopsis**

```
final int ianywhere.qanywhere.client.StatusCodes.FINAL
```

### **Remarks**

The message has achieved a final state.

This code applies to the [STATUS variable](#).

## **LOCAL variable**

### **Synopsis**

```
final int ianywhere.qanywhere.client.StatusCodes.LOCAL
```

### **Remarks**

The message is addressed to the local message store and will not be transmitted to the server.

This code applies to the [TRANSMISSION\\_STATUS variable](#).

## **PENDING variable**

### **Synopsis**

```
final int ianywhere.qanywhere.client.StatusCodes.PENDING
```

### **Remarks**

The message has been sent but not received.

This code applies to the [STATUS variable](#).

## **RECEIVED variable**

### **Synopsis**

```
final int ianywhere.qanywhere.client.StatusCodes.RECEIVED
```

### **Remarks**

The message has been received and acknowledged by the receiver.

This code applies to the [STATUS variable](#).

## RECEIVING variable

### Synopsis

final int `ianywhere.qanywhere.client.StatusCodes.RECEIVING`

### Remarks

The message is in the process of being received, or it was received but not acknowledged.

This code applies to the [STATUS variable](#).

## TRANSMITTED variable

### Synopsis

final int `ianywhere.qanywhere.client.StatusCodes.TRANSMITTED`

### Remarks

The message has been transmitted to the server.

This code applies to the [TRANSMISSION\\_STATUS variable](#).

## TRANSMITTING variable

### Synopsis

final int `ianywhere.qanywhere.client.StatusCodes.TRANSMITTING`

### Remarks

The message is in the process of being transmitted to the server.

This code applies to the [TRANSMISSION\\_STATUS variable](#).

## UNRECEIVABLE variable

### Synopsis

final int `ianywhere.qanywhere.client.StatusCodes.UNRECEIVABLE`

### Remarks

The message has been marked as unreceivable.

The message is either malformed, or there were too many failed attempts to deliver it. This code applies to the [STATUS variable](#).

## **UNTRANSMITTED variable**

### **Synopsis**

final int `ianywhere.qanywhere.client.StatusCodes.UNTRANSMITTED`

### **Remarks**

The message has not been transmitted to the server.

This code applies to the [TRANSMISSION\\_STATUS](#) variable.

## ianywhere.qanywhere.ws package

### Class WSBBase

#### Synopsis

```
public ianywhere.qanywhere.ws.WSBBase
```

#### Remarks

This is the base class for the main web service proxy class generated by the mobile web service compiler.

#### Members

All members of `ianywhere.qanywhere.ws.WSBBase`, including all inherited members.

- ◆ [“clearRequestProperties method” on page 603](#)
- ◆ [“getResult method” on page 603](#)
- ◆ [“getServiceID method” on page 604](#)
- ◆ [“setListener method” on page 604](#)
- ◆ [“setListener method” on page 604](#)
- ◆ [“setProperty method” on page 605](#)
- ◆ [“setQAManager method” on page 605](#)
- ◆ [“setRequestProperty method” on page 606](#)
- ◆ [“setServiceID method” on page 606](#)
- ◆ [“WSBase method” on page 602](#)
- ◆ [“WSBase method” on page 603](#)

### WSBase method

#### Synopsis

```
ianywhere.qanywhere.ws.WSBBase.WSBBase(  
    String iniFile  
)  
throws WSException
```

#### Parameters

- ◆ **iniFile** A file containing configuration properties.

#### Throws

- ◆ Thrown if there is a problem constructing the [“Class WSBBase” on page 602](#).

#### Remarks

Constructor with configuration property file.

Valid configuration properties are:

LOG\_FILE a file to which to log runtime information.

`LOG_LEVEL` a value between 0 and 6 that controls the verbosity of information logged, with 6 being the highest verbosity.

`WS_CONNECTOR_ADDRESS` the address of the web service connector in the MobiLink server. The default `WS_CONNECTOR_ADDRESS` is "ianywhere.connector.webservices\\".

## WSBase method

### Synopsis

```
ianywhere.qanywhere.ws.WSBase.WSBase()  
throws WSException
```

### Throws

- ◆ Thrown if there is a problem constructing the [“Class WSBase” on page 602](#).

### Remarks

Constructor.

## clearRequestProperties method

### Synopsis

```
void ianywhere.qanywhere.ws.WSBase.clearRequestProperties()
```

### Remarks

Clears all request properties that have been set for this [Class WSBase](#).

## getResult method

### Synopsis

```
WSResult ianywhere.qanywhere.ws.WSBase.getResult(  
    String requestID  
)
```

### Parameters

- ◆ `requestID` The ID of the web service request.

### Remarks

Gets a [Class WSResult](#) object that represents the results of a web service request.

### Returns

A [Class WSResult](#) instance representing the results of the web service request.

### See Also

[Class WSStatus](#)

## getServiceID method

### Synopsis

String `ianywhere.qanywhere.ws.WSBase.getServiceID()`

### Remarks

Gets the service ID for this instance of [Class WSBase](#).

### Returns

The service ID.

## setListener method

### Synopsis

```
void ianywhere.qanywhere.ws.WSBase.setListener(  
    String requestID,  
    WSListener listener  
)
```

### Parameters

- ◆ **requestID** The ID of the web service request to which to listen for results.
- ◆ **listener** The listener object that gets called when the result of the given web service request is available.

### Remarks

Sets a listener for the results of a given web service request.

Listeners are typically used to get results of the `asyncXYZ` methods of the service.

To remove a listener, call `setListener` with `null` as the listener.

*Note:* This method replaces the listener set by any previous call to `setListener`.

## setListener method

### Synopsis

```
void ianywhere.qanywhere.ws.WSBase.setListener(  
    WSListener listener  
)
```

### Parameters

- ◆ **listener** The listener object that gets called when the result of a web service request is available.

### Remarks

Sets a listener for the results of all web service requests made by this instance of [Class WSBase](#).

Listeners are typically used to get results of the `asyncXYZ` methods of the service.

To remove a listener, call `setListener` with `null` as the listener.

*Note:* This method replaces the listener set by any previous call to `setListener`.

## setProperty method

### Synopsis

```
void ianywhere.qanywhere.ws.WSBase.setProperty(  
    String property,  
    String val  
)
```

### Parameters

- ◆ **property** The property name to set.
- ◆ **val** The property value.

### Remarks

Sets a configuration property for this instance of [Class WSBase](#).

Configuration properties must be set before any asynchronous or synchronous web service request is made; after which this method has no effect.

Valid configuration properties are:

`LOG_FILE` a file to which to log runtime information.

`LOG_LEVEL` a value between 0 and 6 that controls the verbosity of information logged, with 6 being the highest verbosity.

`WS_CONNECTOR_ADDRESS` the address of the web service connector in the MobiLink server. The default is: "ianywhere.connector.webservices\\".

## setQAManager method

### Synopsis

```
void ianywhere.qanywhere.ws.WSBase.setQAManager(  
    QAManagerBase mgr  
)
```

### Parameters

- ◆ **mgr** The QAManagerBase to use.

### Remarks

Sets the QAManagerBase that is used by this web service client to do web service requests.

*Note:* If you use an EXPLICIT\_ACKNOWLEDGEMENT QAManager, you can acknowledge the result of an asynchronous web service request by calling the acknowledge() method of [Class WSResult](#). The result of a synchronous web service request is automatically acknowledged, even in the case of an EXPLICIT\_ACKNOWLEDGEMENT QAManager. If you use an IMPLICIT\_ACKNOWLEDGEMENT QAManager, the result of any web service request is acknowledged automatically.

## setRequestProperty method

### Synopsis

```
void ianywhere.qanywhere.ws.WSBase.setRequestProperty(  
    String name,  
    Object value  
)
```

### Parameters

- ◆ **name** The property name to set.
- ◆ **value** The property value.

### Remarks

Sets a request property for webservice requests made by this [Class WSBase](#).

A request property is set on each QAMessage that is sent by this [Class WSBase](#), until the property is cleared. A request property is cleared by setting it to a null value. The type of the message property is determined by the class of the value parameter. For example, if value is an instance of Integer, then setIntProperty is used to set the property on the QAMessage.

## setServiceID method

### Synopsis

```
void ianywhere.qanywhere.ws.WSBase.setServiceID(  
    String serviceID  
)
```

### Parameters

- ◆ **serviceID** The service ID.

### Remarks

Sets a user-defined ID for this instance of [Class WSBase](#).

The service ID should be set to a value unique to this instance of [Class WSBase](#). It is used internally to form a queue name for sending and receiving web service requests. Therefore, the service ID should be persisted between application sessions, in order to retrieve results of web service requests made in a previous session.

## Class WSEException

### Synopsis

public `ianywhere.qanywhere.ws.WSEException`

### Derived classes

- ◆ [“Class WSFaultException” on page 608](#)

### Remarks

This class represents an exception that occurred during processing of a web service request.

### Members

All members of `ianywhere.qanywhere.ws.WSEException`, including all inherited members.

- ◆ [“getErrorCode method” on page 608](#)
- ◆ [“WSEException method” on page 607](#)
- ◆ [“WSEException method” on page 607](#)
- ◆ [“WSEException method” on page 608](#)

## WSEException method

### Synopsis

```
ianywhere.qanywhere.ws.WSEException.WSEException(  
    String msg  
)
```

### Parameters

- ◆ **msg** The error message.

### Remarks

Constructs a new exception with the specified error message.

## WSEException method

### Synopsis

```
ianywhere.qanywhere.ws.WSEException.WSEException(  
    String msg,  
    int errorCode  
)
```

### Parameters

- ◆ **msg** The error message.
- ◆ **errorCode** The error code.

### Remarks

Constructs a new exception with the specified error message and error code.

### WSException method

#### Synopsis

```
ianywhere.qanywhere.ws.WSException.WSException(  
    Exception exception  
)
```

#### Parameters

◆ **exception** The exception.

### Remarks

Constructs a new exception.

### getErrorCode method

#### Synopsis

```
int ianywhere.qanywhere.ws.WSException.getErrorCode()
```

### Remarks

Gets the error code associated with this exception.

### Returns

The error code associated with this exception.

## Class WSFaultException

### Synopsis

```
public ianywhere.qanywhere.ws.WSFaultException
```

### Base classes

◆ [“Class WSException” on page 607](#)

### Remarks

This class represents a SOAP Fault exception from the web service connector.

### Members

All members of `ianywhere.qanywhere.ws.WSFaultException`, including all inherited members.

- ◆ [“getErrorCode method” on page 608](#)
- ◆ [“WSException method” on page 607](#)
- ◆ [“WSException method” on page 607](#)
- ◆ [“WSException method” on page 608](#)

- ◆ [“WSFaultException method” on page 609](#)

## WSFaultException method

### Synopsis

```
ianywhere.qanywhere.ws.WSFaultException.WSFaultException(  
    String msg  
)
```

### Parameters

- ◆ **msg** The error message.

### Remarks

Constructs a new exception with the specified error message.

## Interface WSListener

### Synopsis

```
public ianywhere.qanywhere.ws.WSListener
```

### Remarks

This class represents a listener for results of web service requests.

### Members

All members of `ianywhere.qanywhere.ws.WSListener`, including all inherited members.

- ◆ [“onException method” on page 609](#)
- ◆ [“onResult method” on page 610](#)

## onException method

### Synopsis

```
void ianywhere.qanywhere.ws.WSListener.onException(  
    WSException e,  
    WSResult wsResult  
)
```

### Parameters

- ◆ **e** The [“Class WSException” on page 607](#) that occurred during processing of the result.
- ◆ **wsResult** A [“Class WSResult” on page 610](#), from which the request ID may be obtained. Values of this [“Class WSResult” on page 610](#) are not defined.

### Remarks

Called when an exception occurs during processing of the result of an asynchronous web service request.

## onResult method

### Synopsis

```
void ianywhere.qanywhere.ws.WSListener.onResult(  
    WSResult wsResult  
)
```

### Parameters

- ◆ **wsResult** The “[Class WSResult](#)” on page 610 describing the result of a web service request.

### Remarks

Called with the result of an asynchronous web service request.

## Class WSResult

### Synopsis

```
public ianywhere.qanywhere.ws.WSResult
```

### Remarks

This class represents the results of a web service request.

- ◆ It is passed to the [onResult method](#).
- ◆ It is returned by an `asyncXYZ` method of the service proxy generated by the compiler.
- ◆ It is obtained by calling [getResult method](#) with a specific request ID.

A [Class WSResult](#) object is obtained in one of three ways:

### Members

All members of `ianywhere.qanywhere.ws.WSResult`, including all inherited members.

## acknowledge method

### Synopsis

```
void ianywhere.qanywhere.ws.WSResult.acknowledge()
```

### Remarks

Acknowledges that this [Class WSResult](#) has been processed.

This method is only useful when an EXPLICIT\_ACKNOWLEDGEMENT QAManager is being used.

## getArrayValue method

### Synopsis

```
WSSerializable[] i anywhere.q anywhere.ws.WSResult.getArrayValue(  
    String parentName  
)  
throws WSEException
```

### Parameters

- ◆ **parentName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets an array of complex types value from this [Class WSResult](#).

### Returns

The value.

## getBigDecimalArrayValue method

### Synopsis

```
BigDecimal[] i anywhere.q anywhere.ws.WSResult.getBigDecimalArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a BigDecimal array value from this [Class WSResult](#).

### Returns

The value.

## getBigDecimalValue method

### Synopsis

```
BigDecimal ianywhere.qanywhere.ws.WSResult.getBigDecimalValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a BigDecimal value from this [Class WSResult](#).

### Returns

The value.

## getBigIntegerArrayValue method

### Synopsis

```
BigInteger[] ianywhere.qanywhere.ws.WSResult.getBigIntegerArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a BigInteger array value from this [Class WSResult](#).

### Returns

The value.

## getBigIntegerValue method

### Synopsis

```
BigInteger ianywhere.qanywhere.ws.WSResult.getBigIntegerValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a BigInteger value from this [Class WSResult](#).

### Returns

The value.

## getBooleanArrayValue method

### Synopsis

```
Boolean[] ianywhere.qanywhere.ws.WSResult.getBooleanArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a java.lang.Boolean array value from this [Class WSResult](#).

### Returns

The value.

## getBooleanValue method

### Synopsis

```
Boolean ianywhere.qanywhere.ws.WSResult.getBooleanValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a java.lang.Boolean value from this [Class WSResult](#).

### Returns

The value.

## getByteArrayValue method

### Synopsis

```
Byte[] ianywhere.qanywhere.ws.WSResult.getByteArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a java.lang.Byte array value from this [Class WSResult](#).

### Returns

The value.

## getBytesValue method

### Synopsis

```
Byte ianywhere.qanywhere.ws.WSResult.getBytesValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a java.lang.Byte value from this [Class WSResult](#).

### Returns

The value.

## getCharArrayValue method

### Synopsis

```
Character[] ianywhere.qanywhere.ws.WSResult.getCharArrayValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a java.lang.Character array value from this [Class WSResult](#).

### Returns

The value.

## getCharacterValue method

### Synopsis

```
Character ianywhere.qanywhere.ws.WSResult.getCharacterValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a java.lang.Character value from this [Class WSResult](#).

### Returns

The value.

## getDoubleArrayValue method

### Synopsis

```
Double[] ianywhere.qanywhere.ws.WSResult.getDoubleArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a java.lang.Double array value from this [Class WSResult](#).

### Returns

The value.

## getDoubleValue method

### Synopsis

```
Double ianywhere.qanywhere.ws.WSResult.getDoubleValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a `java.lang.Double` value from this [Class WSResult](#).

### Returns

The value.

## getErrorMessage method

### Synopsis

```
String ianywhere.qanywhere.ws.WSResult.getErrorMessage()
```

### Remarks

Gets the error message.

### Returns

The error message.

## getFloatArrayValue method

### Synopsis

```
Float[] ianywhere.qanywhere.ws.WSResult.getFloatArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

**Remarks**

Gets a java.lang.Float array value from this [Class WSRResult](#).

**Returns**

The value.

**getFloatValue method****Synopsis**

```
Float ianywhere.qanywhere.ws.WSRResult.getFloatValue(  
    String elementName  
)  
throws WSEException
```

**Parameters**

◆ **elementName** The element name in the WSDL document of this value.

**Throws**

◆ Thrown if there is a problem getting the value.

**Remarks**

Gets a java.lang.Float value from this [Class WSRResult](#).

**Returns**

The value.

**getIntegerArrayValue method****Synopsis**

```
Integer[] ianywhere.qanywhere.ws.WSRResult.getIntegerArrayValue(  
    String elementName  
)  
throws WSEException
```

**Parameters**

◆ **elementName** The element name in the WSDL document of this value.

**Throws**

◆ Thrown if there is a problem getting the value.

**Remarks**

Gets a java.lang.Integer array value from this [Class WSRResult](#).

## Returns

The value.

## [getIntegerValue method](#)

### Synopsis

```
Integer ianywhere.qanywhere.ws.WSResult.getIntegerValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a `java.lang.Integer` value from this [Class WSResult](#).

## Returns

The value.

## [getLongArrayValue method](#)

### Synopsis

```
Long[] ianywhere.qanywhere.ws.WSResult.getLongArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a `java.lang.Long` array value from this [Class WSResult](#).

## Returns

The value.

## getLongValue method

### Synopsis

```
Long ianywhere.qanywhere.ws.WSResult.getLongValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a java.lang.Long value from this [Class WSResult](#).

### Returns

The value.

## getObjectArrayValue method

### Synopsis

```
Object[] ianywhere.qanywhere.ws.WSResult.getObjectArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets an array of complex types value from this [Class WSResult](#).

### Returns

The value.

## getObjectValue method

### Synopsis

```
Object ianywhere.qanywhere.ws.WSResult.getObjectValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets value of a complex type from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveBooleanArrayValue method

### Synopsis

```
boolean[] ianywhere.qanywhere.ws.WSResult.getPrimitiveBooleanArrayValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a boolean array value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveBooleanValue method

### Synopsis

```
boolean ianywhere.qanywhere.ws.WSResult.getPrimitiveBooleanValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a boolean value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveByteArrayValue method

### Synopsis

```
byte[] ianywhere.qanywhere.ws.WSResult.getPrimitiveByteArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a byte array value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveByteValue method

### Synopsis

```
byte ianywhere.qanywhere.ws.WSResult.getPrimitiveByteValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a byte value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveCharArrayValue method

### Synopsis

```
char[] ianywhere.qanywhere.ws.WSResult.getPrimitiveCharArrayValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a char array value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveCharValue method

### Synopsis

```
char ianywhere.qanywhere.ws.WSResult.getPrimitiveCharValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a char value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveDoubleArrayValue method

### Synopsis

```
double[] ianywhere.qanywhere.ws.WSResult.getPrimitiveDoubleArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a double array value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveDoubleValue method

### Synopsis

```
double ianywhere.qanywhere.ws.WSResult.getPrimitiveDoubleValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a double value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveFloatArrayValue method

### Synopsis

```
float[] ianywhere.qanywhere.ws.WSResult.getPrimitiveFloatArrayValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a float array value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveFloatValue method

### Synopsis

```
float ianywhere.qanywhere.ws.WSResult.getPrimitiveFloatValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a float value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveIntArrayValue method

### Synopsis

```
int[] ianywhere.qanywhere.ws.WSResult.getPrimitiveIntArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets an int array value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveIntValue method

### Synopsis

```
int ianywhere.qanywhere.ws.WSResult.getPrimitiveIntValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets an int value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveLongArrayValue method

### Synopsis

```
long[] ianywhere.qanywhere.ws.WSResult.getPrimitiveLongArrayValue(  
    String elementName  
)  
throws WSException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a long array value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveLongValue method

### Synopsis

```
long ianywhere.qanywhere.ws.WSResult.getPrimitiveLongValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a long value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveShortArrayValue method

### Synopsis

```
short[] ianywhere.qanywhere.ws.WSResult.getPrimitiveShortArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a short array value from this [Class WSResult](#).

### Returns

The value.

## getPrimitiveShortValue method

### Synopsis

```
short ianywhere.qanywhere.ws.WSResult.getPrimitiveShortValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a short value from this [Class WSResult](#).

### Returns

The value.

## getRequestID method

### Synopsis

```
String ianywhere.qanywhere.ws.WSResult.getRequestID()
```

### Remarks

Gets the request ID that this [Class WSResult](#) represents.

This request ID should be persisted between runs of the application if it is desired to obtain a [Class WSResult](#) corresponding to a web service request in a run of the application different from when the request was made.

### Returns

The request ID.

## getShortArrayValue method

### Synopsis

```
Short[] ianywhere.qanywhere.ws.WSResult.getShortArrayValue(  
    String elementName  
)  
throws WSEException
```

**Parameters**

- ◆ **elementName** The element name in the WSDL document of this value.

**Throws**

- ◆ Thrown if there is a problem getting the value.

**Remarks**

Gets a java.lang.Short array value from this [Class WSRResult](#).

**Returns**

The value.

**getShortValue method****Synopsis**

```
Short ianywhere.qanywhere.ws.WSRResult.getShortValue(  
    String elementName  
)  
throws WSEException
```

**Parameters**

- ◆ **elementName** The element name in the WSDL document of this value.

**Throws**

- ◆ Thrown if there is a problem getting the value.

**Remarks**

Gets a java.lang.Short value from this [Class WSRResult](#).

**Returns**

The value.

**getStatus method****Synopsis**

```
int ianywhere.qanywhere.ws.WSRResult.getStatus()
```

**Remarks**

Gets the status of this [Class WSRResult](#).

**Returns**

The status code.

## See Also

[Class WSStatus](#)

## getStringArrayValue method

### Synopsis

```
String[] ianywhere.qanywhere.ws.WSResult.getStringArrayValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a String array value from this [Class WSResult](#).

### Returns

The value.

## getStringValue method

### Synopsis

```
String ianywhere.qanywhere.ws.WSResult.getStringValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets a String value from this [Class WSResult](#).

### Returns

The value.

## getValue method

### Synopsis

```
Object ianywhere.qanywhere.ws.WSResult.getValue(  
    String elementName  
)  
throws WSEException
```

### Parameters

- ◆ **elementName** The element name in the WSDL document of this value.

### Throws

- ◆ Thrown if there is a problem getting the value.

### Remarks

Gets the value of a complex type from this [Class WSResult](#).

### Returns

The value.

## Class WSStatus

### Synopsis

```
public ianywhere.qanywhere.ws.WSStatus
```

### Remarks

This class defines codes for the status of a web service request.

### Members

All members of `ianywhere.qanywhere.ws.WSStatus`, including all inherited members.

- ◆ [“STATUS\\_ERROR variable” on page 633](#)
- ◆ [“STATUS\\_QUEUED variable” on page 634](#)
- ◆ [“STATUS\\_RESULT\\_AVAILABLE variable” on page 634](#)
- ◆ [“STATUS\\_SUCCESS variable” on page 634](#)

## STATUS\_ERROR variable

### Synopsis

```
final int ianywhere.qanywhere.ws.WSStatus.STATUS_ERROR
```

### Remarks

There was an error processing the request.

### **STATUS\_QUEUED variable**

#### **Synopsis**

final int **ianywhere.qanywhere.ws.WSstatus.STATUS\_QUEUED**

#### **Remarks**

The request has been queued for delivery to the server.

### **STATUS\_RESULT\_AVAILABLE variable**

#### **Synopsis**

final int **ianywhere.qanywhere.ws.WSstatus.STATUS\_RESULT\_AVAILABLE**

#### **Remarks**

The result of the request is available.

### **STATUS\_SUCCESS variable**

#### **Synopsis**

final int **ianywhere.qanywhere.ws.WSstatus.STATUS\_SUCCESS**

#### **Remarks**

The request was successful.

CHAPTER 15

# QAnywhere SQL API Reference

## Contents

Message properties, headers, and content ..... 636  
Message store properties ..... 664  
Message management ..... 666

### About this chapter

This chapter describes the QAnywhere SQL API.

QAnywhere SQL is a collection of stored procedures that implement a messaging API in SQL.

## Message properties, headers, and content

This section documents QAnywhere SQL stored procedures that help you set message headers, message content, and message properties.

### Message headers

You can use the following stored procedures to get and set message header information.

☞ For more information about message headers, see [“Message headers” on page 206](#).

### ml\_qa\_getaddress

#### Description

Returns the QAnywhere address of the message.

#### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

#### Return value

The QAnywhere message address as VARCHAR(128). QAnywhere message addresses take the form *id \queue-name*.

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

#### See also

- ◆ [“QAnywhere message addresses” on page 50](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

#### Example

In the following example, a message is received and its address is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @addr varchar(128);
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @addr = ml_qa_getaddress( @msgid );
  message 'message to address ' || @addr || ' received';
  commit;
end
```

## ml\_qa\_getexpiration

### Description

Returns the expiration time of the message.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

### Return value

The expiration time as `TIMESTAMP`. Returns `NULL` if there is no expiration.

### Remarks

After completion of `ml_qa_putmessage`, a message expires if it is not received by the intended recipient in the specified time. The message may then be deleted using default QAnywhere delete rules.

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

### See also

- ◆ [“Message delete rules” on page 239](#)
- ◆ [“Sending QAnywhere messages” on page 66](#)
- ◆ [“ml\\_qa\\_setexpiration” on page 642](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

In the following example, a message is received and the message expiration is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @expires timestamp;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @expires = ml_qa_getexpiration( @msgid );
  message 'message would have expired at ' || @expires || ' if it had not
  been received';
  commit;
end
```

## ml\_qa\_getinreplytoid

### Description

Returns the in-reply-to ID for the message.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

**Return value**

The in-reply-to ID as VARCHAR(128).

**Remarks**

A client can use the InReplyToID header field to link one message with another. A typical use is to link a response message with its request message.

The in-reply-to ID is the ID of the message that this message is replying to.

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setinreplytoid” on page 643](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

**Example**

In the following example, a message is received and the in-reply-to-id of the message is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @inreplytoid varchar(128);
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @inreplytoid = ml_qa_getinreplytoid( @msgid );
  message 'message is likely a reply to the message with id ' ||
@inreplytoid;
  commit;
end
```

**ml\_qa\_getpriority**

**Description**

Returns the priority level of the message.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

**Return value**

The priority level as INTEGER.

**Remarks**

The QAnywhere API defines ten levels of priority value, with 0 as the lowest priority and 9 as the highest. Clients should consider priorities 0-4 as gradations of normal priority and priorities 5-9 as gradations of expedited priority.

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setpriority” on page 644](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

**Example**

In the following example, a message is received and the priority of the message is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @priority integer;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @priority = ml_qa_getpriority( @msgid );
  message 'a message with priority ' || @priority || ' has been received';
  commit;
end
```

**ml\_qa\_getredelivered**

**Description**

Returns a value indicating whether this message has previously been received but not acknowledged.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

**Return value**

The redelivered value as BIT. A value of **1** indicates that the message is being redelivered; **0** indicates that it is not being redelivered.

**Remarks**

A message may be redelivered if it was previously received but not acknowledged. For example, the message was received but the application receiving the message did not complete processing the message content

before it crashed. In these cases, QAnywhere marks the message as redelivered to alert the receiver that the message might be partly processed.

For example, assume that the receipt of a message occurs in three steps:

1. An application using a non-transactional QAnywhere manager receives the message.
2. The application writes the message content and message ID to a database table called T1, and commits the change.
3. The application acknowledges the message.

If the application fails between steps 1 and 2 or between steps 2 and 3, the message is redelivered when the application restarts.

If the failure occurs between steps 1 and 2, you should process the redelivered message by running steps 2 and 3. If the failure occurs between steps 2 and 3, then the message is already processed and you only need to acknowledge it.

To determine what happened when the application fails, you can have the application call `ml_qa_getredelivered` to check if the message has been previously redelivered. Only messages that are redelivered need to be looked up in table T1. This is more efficient than having the application access the received message's message ID to check whether the message is in the table T1, because application failures are rare.

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

### See also

- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

In the following example, a message is received; if the message was previously delivered but not received, the message ID is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @redelivered bit;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @redelivered = ml_qa_getredelivered( @msgid );
  if @redelivered = 1 then
    message 'message with message ID ' || @msgid || ' has been
redelivered';
  end if;
  commit;
end
```

## [ml\\_qa\\_getreplytoaddress](#)

### Description

Returns the address to which a reply to this message should be sent.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

**Return value**

The reply address as VARCHAR(128).

**Remarks**

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setreplytoaddress” on page 645](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

**Example**

In the following example, if the received message has a reply-to address, then a message is sent to the reply-to-address with the content 'message received':

```
begin
  declare @msgid varchar(128);
  declare @rmsgid varchar(128);
  declare @replytoaddr varchar(128);
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @replytoaddr = ml_qa_getreplytoaddress( @msgid );
  if @replytoaddr is not null then
    set @rmsgid = ml_qa_createmessage();
    call ml_qa_settextcontent( @rmsgid, 'message received' );
    call ml_qa_putmessage( @rmsgid, @replytoaddr );
  end if;
  commit;
end
```

**ml\_qa\_gettimestamp**

**Description**

Returns the creation time of the message.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

**Return value**

The message creation time as `TIMESTAMP`.

**Remarks**

The Timestamp header field contains the time a message was created. It is a coordinated universal time (UTC). It is not the time the message was actually transmitted, because the actual send may occur later due to transactions or other client-side queuing of messages.

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

**Example**

In the following example, a message is received and the creation time of the message is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @ts timestamp;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @ts = ml_qa_gettimestamp( @msgid );
  message 'message received with create time: ' || @ts ;
  commit;
end
```

**ml\_qa\_setexpiration**

**Description**

Sets the expiration time for a message.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from <code>ml_qa_createmessage</code> or <code>ml_qa_getmessage</code> .
2	Expiration	TIMESTAMP

**Remarks**

You can read this header after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_getexpiration” on page 637](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)

- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

In the following example, a message is created so that if it is not delivered within the next 3 days it expires:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setexpiration( @msgid, dateadd( day, 3, current timestamp ) );
  call ml_qa_settextcontent( @msgid, 'time-limited offer' );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## ml\_qa\_setinreplytoid

### Description

Sets the in-reply-to ID of this message.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	in-reply-to ID	VARCHAR(128)

### Remarks

An in-reply-to ID is similar to the in-reply-to IDs that are used by email systems to track replies.

Typically you set the in-reply-to ID to be the message ID of the message to which this message is replying, if any.

A client can use the InReplyToID header field to link one message with another. A typical use is to link a response message with its request message.

You cannot alter this header after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_getinreplytoid” on page 637](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

In the following example, when a message is received that contains a reply-to-address, a reply message is created and sent containing the message ID in the in-reply-to-id:

```
begin
  declare @msgid varchar(128);
  declare @rmsgid varchar(128);
```

```

declare @replyaddr varchar(128);
set @msgid = ml_qa_getmessage( 'myaddress' );
set @replyaddr = ml_qa_getreplyaddress( @msgid );
if @replyaddr is not null then
    set @rmsgid = ml_qa_createmessage();
    call ml_qa_settextcontent( @rmsgid, 'message received' );
    call ml_qa_setinreplytoid( @rmsgid, @msgid );
    call ml_qa_putmessage( @rmsgid, @replyaddr );
end if;
commit;
end

```

## ml\_qa\_setpriority

### Description

Sets the priority of a message.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Priority	INTEGER

### Remarks

The QAnywhere API defines ten levels of priority value, with 0 as the lowest priority and 9 as the highest. Clients should consider priorities 0-4 as gradations of normal priority and priorities 5-9 as gradations of expedited priority.

You cannot alter this header after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_getpriority” on page 638](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

The following example sends a high priority message:

```

begin
declare @msgid varchar(128);
set @msgid = ml_qa_createmessage();
call ml_qa_setpriority( @msgid, 9 );
call ml_qa_settextcontent( @msgid, 'priority content' );
call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
commit;
end

```

## ml\_qa\_setreplytoaddress

### Description

Sets the reply-to address of the message.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Reply address	VARCHAR(128)

### Remarks

You cannot alter this header after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_getreplytoaddress” on page 640](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

In the following example, a reply-to-address is added to a message. The recipient of the message can then use that reply-to-address to create a reply.

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setreplytoaddress( @msgid, 'myaddress' );
  call ml_qa_settextcontent( @msgid, 'some content' );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## Message properties

You can use the following stored procedures to get and set your custom message properties, or to get pre-defined message properties.

☞ For more information about message properties, see [“Message properties” on page 209](#).

## ml\_qa\_getbooleanproperty

### Description

Returns the specified message property as a SQL BIT data type.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)

**Return value**

The property value as BIT.

**Remarks**

If the message property value is out of range, then a SQL error with SQLSTATE 22003 occurs.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setbooleanproperty” on page 653](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

**Example**

In the following example, a message is received and the value of the boolean property mybooleanproperty is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @prop bit;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @prop = ml_qa_getbooleanproperty( @msgid, 'mybooleanproperty' );
  message 'message property mybooleanproperty is set to ' || @prop;
  commit;
end
```

**ml\_qa\_getbyteproperty****Description**

Returns the specified message property as a SQL TINYINT data type.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)

**Return value**

The property value as TINYINT.

**Remarks**

If the message property value is out of range, then a SQL error with SQLSTATE 22003 occurs.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setbyteproperty” on page 654](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

**Example**

In the following example, a message is received and the value of byte property mybyteproperty is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @prop tinyint;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @prop = ml_qa_getbyteproperty( @msgid, 'mybyteproperty' );
  message 'message property mybyteproperty is set to ' || @prop;
  commit;
end
```

**ml\_qa\_getdoubleproperty**

**Description**

Returns the specified message property as a SQL DOUBLE data type.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)

**Return value**

The property value as DOUBLE.

**Remarks**

If the message property value is out of range, then a SQL error with SQLSTATE 22003 occurs.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setdoubleproperty” on page 655](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

**Example**

In the following example, a message is received and the value of double property mydoubleproperty is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @prop double;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @prop = ml_qa_getdoubleproperty( @msgid, 'mydoubleproperty' );
  message 'message property mydoubleproperty is set to ' || @prop;
  commit;
end
```

**ml\_qa\_getfloatproperty**

**Description**

Returns the specified message property as a SQL FLOAT data type.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)

**Return value**

The property value as FLOAT.

**Remarks**

If the message property value is out of range, then a SQL error with SQLSTATE 22003 occurs.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setfloatproperty” on page 655](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

- ◆ [“Custom message properties” on page 211](#)

### Example

In the following example, a message is received and the value of float property myfloatproperty is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @prop float;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @prop = ml_qa_getfloatproperty( @msgid, 'myfloatproperty' );
  message 'message property myfloatproperty is set to ' || @prop;
  commit;
end
```

### ml\_qa\_getintproperty

#### Description

Returns the specified message property as a SQL INTEGER data type.

#### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)

#### Return value

The property value as INTEGER.

#### Remarks

If the message property value is out of range, then a SQL error with SQLSTATE 22003 occurs.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

#### See also

- ◆ [“ml\\_qa\\_setintproperty” on page 656](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

### Example

In the following example, a message is received and the value of integer property myintproperty is output to the database console:

```
begin
```

```

declare @msgid varchar(128);
declare @prop integer;
set @msgid = ml_qa_getmessage( 'myaddress' );
set @prop = ml_qa_getintproperty( @msgid, 'myintproperty' );
message 'message property myintproperty is set to ' || @prop;
commit;
end

```

## ml\_qa\_getlongproperty

### Description

Returns the specified message property as a SQL BIGINT data type.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)

### Return value

The property value as BIGINT.

### Remarks

If the message property value is out of range, then a SQL error with SQLSTATE 22003 occurs.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

### See also

- ◆ [“ml\\_qa\\_setlongproperty” on page 657](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

## ml\_qa\_getpropertynames

### Description

Retrieves the property names of the specified message.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

## Remarks

This stored procedure opens a result set over the property names of the specified message. The message ID parameter must be that of a message that has been received.

The result set is a single VARCHAR(128) column, where each row contains the name of a message property. QAnywhere reserved property names (those with the prefix "ias\_" or "QA") are not returned.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

## See also

- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

## Example

The following example declares a cursor over the result set of property names for a message that has the message ID msgid. It then gets a message that has the address someAddress; opens a cursor to access the property names of the message; and finally fetches the next property name.

```
begin
  declare prop_name_cursor cursor for
    call ml_qa_getpropertynames( @msgid );
  declare @msgid varchar(128);
  declare @name varchar(128);

  set @msgid = ml_qa_getmessage( 'someAddress' );
  open prop_name_cursor;
  lp: loop
    fetch next prop_name_cursor into name;
    if sqlcode <> 0 then leave lp end if;
    ...
  end loop;
  close prop_name_cursor;
end
```

## ml\_qa\_getshortproperty

### Description

Returns the specified message property as a SQL SMALLINT data type.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)

**Return value**

The property value as SMALLINT.

**Remarks**

If the message property value is out of range, then a SQL error with SQLSTATE 22003 occurs.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setshortproperty” on page 658](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

**Example**

In the following example, a message is received and the value of the short property myshortproperty is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @prop smallint;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @prop = ml_qa_getshortproperty( @msgid, 'myshortproperty' );
  message 'message property myshortproperty is set to ' || @prop;
  commit;
end
```

**ml\_qa\_getstringproperty**

**Description**

Returns the specified message property as a SQL LONG VARCHAR data type.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)

**Return value**

The property value as LONG VARCHAR.

**Remarks**

If the message property value is out of range, then a SQL error with SQLSTATE 22003 occurs.

You can read this property after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setstringproperty” on page 658](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

**Example**

In the following example, a message is received and the value of the string property mystringproperty is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @prop long varchar;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @prop = ml_qa_getstringproperty( @msgid, 'mystringproperty' );
  message 'message property mystringproperty is set to ' || @prop;
  commit;
end
```

**ml\_qa\_setbooleanproperty**

**Description**

Sets the specified message property from a SQL BIT data type.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)
3	Property value	BIT

**Remarks**

You cannot alter this property after the message has been sent.

**See also**

- ◆ [“ml\\_qa\\_getbooleanproperty” on page 645](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

## Example

In the following example, a message is created, the boolean properties `mybooleanproperty1` and `mybooleanproperty2` are set, and the message is sent to the address `someclient\someaddress`:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setbooleanproperty( @msgid, 'mybooleanproperty1', 0 );
  call ml_qa_setbooleanproperty( @msgid, 'mybooleanproperty2', 1 );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## ml\_qa\_setbyteproperty

### Description

Sets the specified message property from a SQL TINYINT data type.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from <code>ml_qa_createmessage</code> or <code>ml_qa_getmessage</code> .
2	Property name	VARCHAR(128)
3	Property value	TINYINT

### Remarks

You cannot alter this property after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_getbyteproperty” on page 646](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

## Example

In the following example, a message is created, the byte properties `mybyteproperty1` and `mybyteproperty2` are set, and the message is sent to the address `someclient\someaddress`:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setbyteproperty( @msgid, 'mybyteproperty1', 0 );
  call ml_qa_setbyteproperty( @msgid, 'mybyteproperty2', 255 );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## ml\_qa\_setdoubleproperty

### Description

Sets the specified message property from a SQL DOUBLE data type.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)
3	Property value	DOUBLE

### Remarks

You cannot alter this property after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_getdoubleproperty” on page 647](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

### Example

In the following example, a message is created, the double properties mydoubleproperty1 and mydoubleproperty2 are set, and the message is sent to the address someclient\someaddress:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setdoubleproperty( @msgid, 'mydoubleproperty1', -12.34e-56 );
  call ml_qa_setdoubleproperty( @msgid, 'mydoubleproperty2', 12.34e56 );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## ml\_qa\_setfloatproperty

### Description

Sets the specified message property from a SQL FLOAT data type.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

Item	Description	Remarks
2	Property name	VARCHAR(128)
3	Property value	FLOAT

**Remarks**

You cannot alter this property after the message has been sent.

**See also**

- ◆ [“ml\\_qa\\_getfloatproperty” on page 648](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

**Example**

In the following example, a message is created, the float properties myfloatproperty1 and myfloatproperty2 are set, and the message is sent to the address someclient\someaddress:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setfloatproperty( @msgid, 'myfloatproperty1', -1.3e-5 );
  call ml_qa_setfloatproperty( @msgid, 'myfloatproperty2', 1.3e5 );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

**ml\_qa\_setintproperty****Description**

Sets the specified message property from a SQL INTEGER data type.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)
3	Property value	INTEGER

**Remarks**

You cannot alter this property after the message has been sent.

**See also**

- ◆ [“ml\\_qa\\_getintproperty” on page 649](#)

- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

### Example

In the following example, a message is created, the integer properties myintproperty1 and myintproperty2 are set, and the message is sent to the address someclient\someaddress:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setintproperty( @msgid, 'myintproperty1', -1234567890 );
  call ml_qa_setintproperty( @msgid, 'myintproperty2', 1234567890 );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

### ml\_qa\_setlongproperty

#### Description

Sets the specified message property from a SQL BIGINT data type.

#### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)
3	Property value	BIGINT

#### Remarks

You cannot alter this property after the message has been sent.

#### See also

- ◆ [“ml\\_qa\\_getlongproperty” on page 650](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

### Example

In the following example, a message is created, the long properties mylongproperty1 and mylongproperty2 are set, and the message is sent to the address someclient\someaddress:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setlongproperty( @msgid, 'mylongproperty1',
-12345678900987654321 );
```

```

        call ml_qa_setlongproperty( @msgid, 'mylongproperty2',
12345678900987654321 );
        call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
        commit;
    end

```

## ml\_qa\_setshortproperty

### Description

Sets the specified message property from a SQL SMALLINT data type.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)
3	Property value	SMALLINT

### Remarks

You cannot alter this property after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_getshortproperty” on page 651](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

### Example

In the following example, a message is created, the short properties myshortproperty1 and myshortproperty2 are set, and the message is sent to the address someclient\someaddress:

```

begin
    declare @msgid varchar(128);
    set @msgid = ml_qa_createmessage();
    call ml_qa_setshortproperty( @msgid, 'myshortproperty1', -12345 );
    call ml_qa_setshortproperty( @msgid, 'myshortproperty2', 12345 );
    call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
    commit;
end

```

## ml\_qa\_setstringproperty

### Description

Sets the specified message property from a SQL LONG VARCHAR data type.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Property name	VARCHAR(128)
3	Property value	LONG VARCHAR

### Remarks

You cannot alter this property after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_getstringproperty” on page 652](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“Custom message properties” on page 211](#)

### Example

In the following example, a message is created, the string properties mystringproperty1 and mystringproperty2 are set, and the message is sent to the address someclient\someaddress:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setstringproperty( @msgid, 'mystringproperty1', 'c:\\temp' );
  call ml_qa_setstringproperty( @msgid, 'mystringproperty2', 'first line
\nsecond line' );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## Message content

You can use the following stored procedures to get and set message content.

### [ml\\_qa\\_getbinarycontent](#)

#### Description

Returns the message content of a binary message.

#### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

**Return value**

The message content as LONG BINARY.

If the message has text content rather than binary content, this stored procedure returns NULL.

You can read this content after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_setbinarycontent” on page 662](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getcontentclass” on page 660](#)

**Example**

In the following example, a message's encrypted content is decrypted and output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @content long binary;
  declare @plaintext long varchar;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @content = ml_qa_getbinarycontent( @msgid );
  set @plaintext = decrypt( @content, 'mykey' );
  message 'message content decrypted: ' || @plaintext;
  commit;
end
```

**ml\_qa\_getcontentclass****Description**

Returns the message type (text or binary).

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

**Return value**

The content class as INTEGER.

The return value can be:

- ◆ **1** indicates that the message content is binary and should be read using the stored procedure ml\_qa\_getbinarycontent.
- ◆ **2** indicates that the message content is text and should be read using the stored procedure ml\_qa\_gettextcontent.

**Remarks**

You can read this content after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getbinarycontent” on page 659](#)
- ◆ [“ml\\_qa\\_gettextcontent” on page 661](#)

**Example**

In the following example, a message is received and the content is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @contentclass integer;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @contentclass = ml_qa_getcontentclass( @msgid );
  if @contentclass = 1 then
    message 'message binary is ' || ml_qa_getbinarycontent( @msgid );
  elseif @contentclass = 2 then
    message 'message text is ' || ml_qa_gettextcontent( @msgid );
  end if;
  commit;
end
```

**ml\_qa\_gettextcontent**

**Description**

Returns the message content of a text message.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.

**Return value**

The text content as LONG VARCHAR.

If the message has binary content rather than text content, this stored procedure returns NULL.

**Remarks**

You can read this content after a message is received and until a rollback or commit occurs; after that you cannot read it.

**See also**

- ◆ [“ml\\_qa\\_settextcontent” on page 663](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)

- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getcontentclass” on page 660](#)

### Example

In the following example, the content of a message is output to the database console:

```
begin
  declare @msgid varchar(128);
  declare @content long binary;
  set @msgid = ml_qa_getmessage( 'myaddress' );
  set @content = ml_qa_gettextcontent( @msgid );
  message 'message content: ' || @content ;
  commit;
end
```

## ml\_qa\_setbinarycontent

### Description

Sets the binary content of the message.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Content	LONG BINARY

### Remarks

You cannot alter this content after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_getbinarycontent” on page 659](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

In the following example, a message is created with encrypted content and sent:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_setbinarycontent( @msgid, encrypt( 'my secret message',
  'mykey' ) );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## ml\_qa\_settextcontent

### Description

Sets the text content of the message.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Content	LONG VARCHAR

### Remarks

You cannot alter this content after the message has been sent.

### See also

- ◆ [“ml\\_qa\\_gettextcontent” on page 661](#)
- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

In the following example, a message is created and then set with the given content:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_settextcontent( @msgid, 'my simple message' );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## Message store properties

You can use the following stored procedures to get and set properties for client message stores.

For more information about message store properties, see [“Client message store properties” on page 215](#).

### ml\_qa\_getstoreproperty

#### Description

Returns a client message store property.

#### Parameters

Item	Description	Remarks
1	Property name	VARCHAR(128)

#### Return value

The property value as LONG VARCHAR.

#### Remarks

Client message store properties are readable from every connection to this client message store.

#### See also

- ◆ [“ml\\_qa\\_setstoreproperty” on page 664](#)

#### Example

The following example gets the current synchronization policy of this message store and outputs it to the database console:

```
begin
  declare @policy varchar(128);
  set @policy = ml_qa_getstoreproperty( 'policy' );
  message 'the current policy for synchronizing this message store is ' ||
  @policy;
end
```

### ml\_qa\_setstoreproperty

#### Description

Sets a client message store property.

#### Parameters

Item	Description	Remarks
1	Property name	VARCHAR(128)

Item	Description	Remarks
2	Property value	SMALLINT

**Remarks**

Client message store properties are readable from every connection to this client message store. The values are synchronized up to the server, as well, where they can be used in transmission rules.

**See also**

- ◆ [“ml\\_qa\\_getstoreproperty” on page 664](#)

**Example**

The following example sets the synchronization policy to automatic for the message store:

```
begin
  call ml_qa_setstoreproperty( 'policy', 'automatic' );
  commit;
end
```

## Message management

You can use the following stored procedures to manage your QAnywhere client transactions.

### ml\_qa\_createmessage

#### Description

Returns the message ID of a new message.

#### Return value

The message ID of the new message.

#### Remarks

Use this stored procedure to create a message. Once created, you can associate content, properties, and headers with this message and then send the message.

You can associate content, properties, and headers using any of the QAnywhere stored procedures starting with ml\_qa\_set. For example, use ml\_qa\_setbinarycontent or ml\_qa\_settextcontent to create a binary or text message.

#### See also

- ◆ [“Message headers” on page 636](#)
- ◆ [“Message properties” on page 645](#)
- ◆ [“Message content” on page 659](#)

#### Example

The following example creates a message, sets the message content, and sends the message to the address someclient\someaddress:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_settextcontent( @msgid, 'some content' );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

### ml\_qa\_getmessage

#### Description

Returns the message ID of the next message that is queued for the given address, blocking until one is queued.

**Parameters**

Item	Description	Remarks
1	Address	VARCHAR(128)

**Return value**

The message ID as VARCHAR(128).

Returns NULL if there is no queued message for this address.

**Remarks**

Use this stored procedure to check synchronously whether there is a message waiting for the specified QAnywhere message address. If you want a SQL procedure to be called asynchronously as soon as a message is available for a specified QAnywhere address, use the Listener.

This stored procedure blocks until a message is queued.

☞ For information about avoiding blocking, see [“ml\\_qa\\_getmessagenowait” on page 668](#) or [“ml\\_qa\\_getmessagetimeout” on page 669](#).

The message corresponding to the returned message ID is not considered to be received until the current transaction is committed. Once the receive is committed, the message cannot be received again by this or any other QAnywhere API. Similarly, a rollback of the current transaction means that the message is not received, so subsequent calls to ml\_qa\_getmessage may return the same message ID.

The properties and content of the received message can be read by the various ml\_qa\_get stored procedures until a commit or rollback is executed on the current transaction. Once a commit or rollback is executed on the current transaction, the message data is no longer readable. Before committing, you should store any data you need from the message as tabular data or in SQL variables.

**See also**

- ◆ [“ml\\_qa\\_getmessagenowait” on page 668](#)
- ◆ [“ml\\_qa\\_getmessagetimeout” on page 669](#)
- ◆ [“Message headers” on page 636](#)
- ◆ [“Message properties” on page 645](#)
- ◆ [“Message content” on page 659](#)

**Example**

The following example displays the content of all messages sent to the address myaddress:

```
begin
  declare @msgid varchar(128);
  loop
    set @msgid = ml_qa_getmessage( 'myaddress' );
    message 'a message with content ' || ml_qa_gettextcontent( @msgid )
  || ' has been received';
    commit;
  end loop;
end
```

## ml\_qa\_getmessagenowait

### Description

Returns the message ID of the next message that is currently queued for the given address.

### Parameters

Item	Description	Remarks
1	Address	VARCHAR(128)

### Return value

The message ID as VARCHAR(128).

Returns the message ID of the next message that is queued for the given address. Returns NULL if there is no queued message for this address.

### Remarks

Use this stored procedure to check synchronously whether there is a message waiting for the specified QAnywhere message address. If you want a SQL procedure to be called asynchronously as soon as a message is available for a specified QAnywhere address, use the Listener.

 For information on blocking until a message is available, see [“ml\\_qa\\_getmessage” on page 666](#) and [“ml\\_qa\\_getmessagetimeout” on page 669](#).

The message corresponding to the returned message is not considered to be received until the current transaction is committed. Once the receive is committed, the message cannot be received again by this or any other QAnywhere API. Similarly, a rollback of the current transaction means that the message is not received, so subsequent calls to ml\_qa\_getmessage may return the same message ID.

The properties and content of the received message can be read by the various ml\_qa\_get stored procedures until a commit or rollback is executed on the current transaction. Once a commit or rollback is executed on the current transaction, the message data is no longer readable. Before committing, you should store any data you need from the message as tabular data or in SQL variables.

### See also

- ◆ [“QAnywhere message addresses” on page 50](#)
- ◆ [“Listeners” \[MobiLink - Server-Initiated Synchronization\]](#)
- ◆ [“ml\\_qa\\_getmessagetimeout” on page 669](#)
- ◆ [“Message headers” on page 636](#)
- ◆ [“Message properties” on page 645](#)
- ◆ [“Message content” on page 659](#)

### Example

The following example displays the content of all messages that are queued at the address myaddress until all such messages are read (it is generally more efficient to commit after the last message has been read, rather than after each message is read):

```

begin
  declare @msgid varchar(128);
  loop
    set @msgid = ml_qa_getmessagenowait( 'myaddress' );
    if @msgid is null then leave end if;
    message 'a message with content ' || ml_qa_gettextcontent( @msgid )
  || ' has been received';
  end loop;
  commit;
end

```

## ml\_qa\_getmessage timeout

### Description

Waits for the specified timeout period to return the message ID of the next message that is queued for the given address.

### Parameters

Item	Description	Remarks
1	Address	VARCHAR(128)
2	Timeout in milliseconds	INTEGER

### Return value

The message ID as VARCHAR(128).

Returns NULL if there is no queued message for this address within the timeout period.

### Remarks

Use this stored procedure to check synchronously whether there is a message waiting for the specified QAnywhere message address. If you want a SQL procedure to be called asynchronously as soon as a message is available for a specified QAnywhere address, use the Listener.

The message corresponding to the returned message is not considered to be received until the current transaction is committed. Once the receive is committed, the message cannot be received again by this or any other QAnywhere API. Similarly, a rollback of the current transaction means that the message is not received, so subsequent calls to ml\_qa\_getmessage may return the same message ID.

The properties and content of the received message can be read by the various ml\_qa\_get stored procedures until a commit or rollback is executed on the current transaction. Once a commit or rollback is executed on the current transaction, the message data is no longer readable. Before committing, you should store any data you need from the message as tabular data or in SQL variables.

### See also

- ◆ [“ml\\_qa\\_getmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessagenowait” on page 668](#)

### Example

The following example outputs the content of all messages sent to the address myaddress to the database console, and updates the database console every 10 seconds if no message has been received:

```
begin
  declare @msgid varchar(128);
  loop
    set @msgid = ml_qa_getmessage(timeout( 'myaddress', 10000 ));
    if @msgid is null then
      message 'waiting for a message...';
    else
      message 'a message with content ' || ml_qa_gettextcontent( @msgid )
      || ' has been received';
      commit;
    end if;
  end loop;
end
```

## ml\_qa\_grant\_messaging\_permissions

### Description

Grants permission to other users to use QAnywhere stored procedures.

### Parameters

Item	Description	Remarks
1	Database user ID	VARCHAR(128)

### Remarks

Only users with DBA privilege automatically have permission to execute the QAnywhere stored procedures. Other users must be granted permission by having a user with DBA privileges run this stored procedure.

This procedure adds the user to a group called ml\_qa\_message\_group and gives them execute permissions on all QAnywhere stored procedures.

### Example

For example, to grant messaging permissions to a user with the database ID user1, execute the following SQL code:

```
call dbo.ml_qa_grant_messaging_permissions( 'user1' )
```

## ml\_qa\_listener\_queue

### Description

Create a stored procedure named **ml\_qa\_listener\_queue** (where *queue* is the name of a message queue) to receive messages asynchronously.

**Parameters**

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from the QAnywhere Listener.

**Remarks****Note**

This procedure is different from all the other QAnywhere stored procedures in that the stored procedure is not provided. If you create a stored procedure named **ml\_qa\_listener\_queue**, where *queue* is a message queue, then it is used by QAnywhere.

Although messages can be received synchronously on a connection, it is often convenient to receive messages asynchronously. You can create a stored procedure that is called when a message has been queued on a particular address. The name of this procedure must be **ml\_qa\_listener\_queue**, where *queue* is the message queue. When this procedure exists, the procedure is called whenever a message is queued on the given address.

This procedure is called from a separate connection. As long as a SQL error does not occur while this procedure is executing, the message is automatically acknowledged and committed.

Do not commit or rollback within this procedure.

The queue name is part of the QAnywhere address. For more information, see [“QAnywhere message addresses”](#) on page 50.

**See also**

- ◆ [“Receiving messages asynchronously”](#) on page 76
- ◆ [“Receiving messages synchronously”](#) on page 75
- ◆ [“ml\\_qa\\_createmessage”](#) on page 666
- ◆ [“ml\\_qa\\_getmessage”](#) on page 666

**Example**

The following example creates a procedure that is called whenever a message is queued on the address named `executesql`. In this example, the procedure assumes that the content of the message is a SQL statement that it can execute against the current database.

```
CREATE PROCEDURE ml_qa_listener_executesql(IN @msgid VARCHAR(128))
begin
    DECLARE @execstr LONG VARCHAR;
    SET @execstr = ml_qa_gettextcontent( @msgid );
    EXECUTE IMMEDIATE @execstr;
end
```

## ml\_qa\_putmessage

### Description

Sends a message.

### Parameters

Item	Description	Remarks
1	Message ID	VARCHAR(128). You can obtain the message ID from ml_qa_createmessage or ml_qa_getmessage.
2	Address	VARCHAR(128)

### Remarks

The message ID you specify must have been previously created using ml\_qa\_createmessage. Only content, properties and headers associated with the message ID before the call to ml\_qa\_putmessage are sent with the message. Any added after the ml\_qa\_putmessage are ignored.

A commit is required before the message is actually queued for sending.

### See also

- ◆ [“ml\\_qa\\_createmessage” on page 666](#)
- ◆ [“ml\\_qa\\_getmessage” on page 666](#)

### Example

In the following example, a message is created with the content 'a simple message' and sent to the address someclient\someaddress:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_settextcontent( @msgid, 'a simple message' );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  commit;
end
```

## ml\_qa\_triggersendreceive

### Description

Triggers a synchronization of messages with the MobiLink server.

### Remarks

Normally, message synchronization is handled by the QAnywhere Agent. However, if the synchronization policy is ondemand, then it is the application's responsibility to trigger the synchronization of messages. You can do so using this stored procedure. The trigger does not take effect until the current transaction is committed.

**Example**

In the following example, a message is sent and the transmission of the message is immediately initiated:

```
begin
  declare @msgid varchar(128);
  set @msgid = ml_qa_createmessage();
  call ml_qa_settextcontent( @msgid, 'my simple message' );
  call ml_qa_putmessage( @msgid, 'someclient\someaddress' );
  call ml_qa_triggersendreceive();
  commit;
end
```
