IMSL C Stat Library

The IMSL C Stat Library is a library of C functions useful in scientific programming. Each function is designed and documented to be used in research activities as well as by technical specialists.

Organization of the Documentation

This manual contains a concise description of each function. All information pertaining to a particular function is in one place within a chapter.

Each chapter begins with an introduction followed by a table of contents listing the functions included in the chapter. Documentation of the functions consists of the following information:

- Section Name: **Usually, the common root for the type *float* and type *double* versions of the function.**
- Purpose: **A statement of the purpose of the function.**
- Synopsis: **The form for referencing the subprogram with required arguments listed.**

  Required Arguments: A description of the required arguments in the order of their occurrence.

  Input: Argument must be initialized; it is not changed by the function.

Input/Output: Argument must be initialized; the function returns output through this argument. The argument cannot be a constant or an expression.

Output: No initialization is necessary. The argument cannot be a constant or an expression; the function returns output through this argument.

- **Return Value**: The value returned by the function.
- **Synopsis with Optional Arguments**: The form for referencing the function with both required and optional arguments listed.
- **Optional Arguments**: A description of the optional arguments in the order of their occurrence.
- **Description**: A description of the algorithm and references to detailed information. In many cases, other IMSL functions with similar or complementary functions are noted.
- **Errors**: Listing of any errors that may occur with a particular function. A discussion on error types is given in the "User Errors" section of the Reference Material. The errors are listed by their type as follows:

  Informational Errors: List of informational errors that may occur with the function.

  Alert Errors: List of alert errors that may occur with the function.

  Warning Errors: List of warning errors that may occur with the function.

  Fatal Errors: List of fatal errors that may occur with the function.

  References: References are listed alphabetically by author.

Finding the Right Function

The C Stat Library documentation is organized into chapters; each chapter contains functions with similar computational or analytical capabilities. To locate the right function for a given problem, use the table of contents located in each chapter introduction.

Naming Conventions

Most functions are available in both a type *float* and a type *double* version, with names of the two versions sharing a common root. Some functions are also available in type *int*. The following list is of each type and the corresponding prefix of the function name in which multiple type versions exist:

Type	Prefix
float	`imsls_f_`
double	`imsls_d_`
int	`imsls_i_`

The section names for the functions contain only the common root to make finding the functions easier.

Where appropriate, the same variable name is used consistently throughout the C Stat Library. For example, `anova_table` denotes the array containing the analysis of variance statistics and `y` denotes a vector of responses for a dependent variable.

When writing programs accessing the C Stat Library, choose C names that do not conflict with IMSL external names. The careful user can avoid any conflicts with IMSL names if, in choosing names, the following rule is observed:

- **Do not choose a name beginning with "`imsls_`" in any combination of uppercase or lowercase characters.**

Error Handling, Underflow, and Overflow

The functions in the C Stat Library attempt to detect and report errors and invalid input. This error-handling capability provides automatic protection for the user without requiring the user to make any specific provisions for the treatment of error conditions. Errors are classified according to severity and are assigned a code number. By default, errors of moderate or higher severity result in messages being automatically printed by the function. Moreover, errors of highest severity cause program execution to stop. The severity level, as well as the general nature of the error, is designated by an "error type" with symbolic names `IMSLS_FATAL`, `IMSLS_WARNING`, etc. See the section "User Errors" in the Reference Material for further details.

In general, the C Stat Library codes are written so that computations are not affected by underflow, provided the system (hardware or software) replaces an underflow with the value 0. Normally, system error messages indicating underflow can be ignored.

IMSL codes also are written to avoid overflow. A program that produces system error messages indicating overflow should be examined for programming errors such as incorrect input data, mismatch of argument types, or improper dimensions.

In many cases, the documentation for a function points out common pitfalls that can lead to failure of the algorithm.

Garch Modeling

Computes estimates of the parameters of a GARCH (*p*,*q*) model ..... **garch** 62

Usage Notes

The functions in this chapter assume the time series does not contain any missing observations. If missing values are present, they should be set to NaN, and the routine will return an appropriate error message. To enable fitting of the model, the missing values must be replaced by appropriate estimates.

Time Domain Methodology

Once the data are transformed to stationarity, a tentative model in the time domain is often proposed and parameter estimation, diagnostic checking and forecasting are performed.

ARIMA Model (Autoregressive Integrated Moving Average)

A small, yet comprehensive, class of stationary time-series models consists of the nonseasonal ARMA processes defined by

$$\phi(B)\,(W\mathrm{t} - \mu) = \theta(B)A\mathrm{t}, \qquad t \in Z$$

where $Z = \{..., -2, -1, 0, 1, 2, ...\}$ denotes the set of integers, B is the backward shift operator defined by $B\mathrm{k}W\mathrm{t} = W\text{t-k}$, μ is the mean of Wt, and the following equations are true:

$$\phi(B) = 1 - \phi 1B - \phi 2B2 - ... - \phi \mathrm{p}B\mathrm{p},\ p \geq 0$$

$$\theta(B) = 1 - \theta 1B - \theta 2B2 - ... - \theta \mathrm{q}B\mathrm{q},\ q \geq 0$$

The model is of order (p, q) and is referred to as an ARMA (p, q) model.

An equivalent version of the ARMA (*p*, *q*) model is given by

$$\phi(B)\ W\mathrm{t} = \theta 0 + \theta(B)A\mathrm{t}, \qquad t \in Z$$

where $\theta 0$ is an overall constant defined by the following:

$$\theta_0 = \mu\left(1 - \sum_{i=1}^{p}\phi_i\right)$$

See Box and Jenkins (1976, pp. 92–93) for a discussion of the meaning and usefulness of the overall constant.

If the "raw" data, {*Z*t}, are homogeneous and nonstationary, then differencing using `imsls_f_difference` induces stationarity, and the model is called ARIMA (AutoRegressive Integrated Moving Average). Parameter estimation is performed on the stationary time series *W*t, = $\nabla \mathrm{d}Z\mathrm{t}$, where $\nabla \mathrm{d} = (1 - B)\mathrm{d}$ is the backward difference operator with period 1 and order *d*, d > 0.

Typically, the method of moments includes argument `IMSLS_METHOD_OF_MOMENTS` in a call to function `imsls_f_arma` for preliminary parameter estimates. These estimates can be used as initial values into the least-squares procedure by including argument `IMSLS_LEAST_SQUARES` in a call to function `imsls_f_arma`. Other initial estimates provided by the user can be used. The least-squares procedure can be used to compute conditional or unconditional least-squares estimates of the parameters, depending on the choice of the backcasting length. The functions for preliminary parameter estimation, least-squares parameter estimation, and forecasting follow the approach of Box and Jenkins (1976, Programs 2–4, pp. 498–509).

arma

Computes least-square estimates of parameters for an ARMA model.

Synopsis

float `*imsls_f_arma` (*int* `n_observations`, *float* `z[]`, *int* `p`, *int* `q`, ..., 0)

The type *double* function is `imsls_d_arma`.

Required Arguments

int `n_observations` (Input)
Number of observations.

float `z[]` (Input)
Array of length `n_observations` containing the observations.

int `p` (Input)
Number of autoregressive parameters.

int `q` (Input)
Number of moving average parameters.

Return Value

Pointer to an array of length 1 + *p* + *q* with the estimated constant, AR, and MA parameters. If `IMSLS_NO_CONSTANT` is specified, the 0-th element of this array is 0.0.

Description

Function `imsls_f_arma` computes estimates of parameters for a nonseasonal ARMA model given a sample of observations, {*W*t}, for *t* = 1, 2, ..., *n*, where *n* = `n_observations`. There are two methods, method of moments and least squares, from which to choose. The default is method of moments.

Two methods of parameter estimation, method of moments and least squares, are provided. The user can choose the method of moments algorithm with the optional argument `IMSLS_METHOD_OF_MOMENTS`. The least-squares algorithm is used if the user specifies `IMSLS_LEAST_SQUARES`. If the user wishes to use the least-squares algorithm, the preliminary estimates are the method of moments estimates by default. Otherwise, the user can input initial estimates by specifying optional argument `IMSLS_INITIAL_ESTIMATES`. The following table lists the appropriate optional arguments for both the

method of moments and least-squares algorithm:

Method of Moments only	Least Squares only	Both Method of Moments and Least Squares
IMSLS_METHOD_OF_MOMENTS	IMSLS_LEAST_SQUARES	IMSLS_RELATIVE_ERROR
	IMSLS_CONSTANT (or IMSLS_NO_CONSTANT)	IMSLS_MAX_ITERATIONS
	IMSLS_AR_LAGS	IMSLS_MEAN_ESTIMATE
	IMSLS_MA_LAGS	IMSLS_AUTOCOV(_USER)
	IMSLS_BACKCASTING	IMSLS_RETURN_USER
	IMSLS_CONVERGENCE_TOLERANCE	IMSLS_ARMA_INFO
	IMSLS_INITIAL_ESTIMATES	
	IMSLS_RESIDUAL (_USER)	
	IMSLS_PARAM_EST_COV (_USER)	
	IMSLS_SS_RESIDUAL	

Method of Moments Estimation

Suppose the time series {*Z*t} is generated by an ARMA (*p*, *q*) model of the form

$$\phi(B)Z\text{t} = \theta 0 + \theta(B)A\text{t}$$

for $t \in \{0, \pm 1, \pm 2, \ldots\}$

Let $\hat{\mu}$ = z_mean be the estimate of the mean μ of the time series{*Z*t}, where $\hat{\mu}$ equals the following:

$$\hat{\mu} = \begin{cases} \mu & \text{for } \mu \text{ known} \\ \dfrac{1}{n}\sum_{t=1}^{n} Z_t & \text{for } \mu \text{ unknown} \end{cases}$$

The autocovariance function is estimated by

$$\hat{\sigma}(k) = \frac{1}{n}\sum_{t=1}^{n-k}(Z_t - \hat{\mu})(Z_{t+k} - \hat{\mu})$$

for k = 0, 1, ..., K, where $K = p + q$. Note that $\hat{\sigma}$ (0) is an estimate of the sample variance.

Given the sample autocovariances, the function computes the method of moments estimates of the autoregressive parameters using the extended Yule-Walker equations as follows:

$$\hat{\Sigma}\hat{\phi} = \hat{\sigma}$$

where

$$\hat{\phi} = \left(\hat{\phi}_1, \ldots, \hat{\phi}_p\right)^T$$
$$\hat{\Sigma}_{ij} = \hat{\sigma}\left(|\, q + i - j\,|\right),\ i, j = 1, \ldots, p$$
$$\hat{\sigma}_i = \hat{\sigma}\left(q + i\right), \qquad i = 1, \ldots, p$$

The overall constant $\theta 0$ is estimated by the following:

$$\hat{\theta}_0 = \begin{cases} \hat{\mu} & \text{for } p = 0 \\ \hat{\mu}\left(1 - \sum_{i=1}^{p}\hat{\phi}_i\right) & \text{for } p > 0 \end{cases}$$

The moving average parameters are estimated based on a system of nonlinear equations given $K = p + q + 1$ autocovariances, $\sigma(k)$ for k = 1, ..., K, and p autoregressive parameters ϕi for i = 1, ..., p.

Let Z′t = $\phi(B)$Zt. The autocovariances of the derived moving average process Z′t = $\theta(B)$At are estimated by the following relation:

$$\hat{\sigma}'(k) = \begin{cases} \hat{\sigma}(k) & \text{for } p = 0 \\ \sum_{i=0}^{p} \sum_{j=0}^{p} \hat{\phi}_i \hat{\phi}_j \left(\hat{\sigma}\left(|k + i - j| \right) \right) & \text{for } p \geq 1, \hat{\phi}_0 \equiv -1 \end{cases}$$

The iterative procedure for determining the moving average parameters is based on the relation

$$\sigma(k) = \begin{cases} \left(1 + \theta_1^2 + \ldots + \theta_q^2\right)\sigma_A^2 & \text{for } k = 0 \\ \left(-\theta_k + \theta_1\theta_{k+1} + \ldots + \theta_{q-k}\theta_q\right)\sigma_A^2 & \text{for } k \geq 1 \end{cases}$$

where $\sigma(k)$ denotes the autocovariance function of the original *Z*t process.

Let $\tau = (\tau 0, \tau 1, \ldots, \tau q)\mathrm{T}$ and $f = (f0, f1, \ldots, fq)\mathrm{T}$, where

$$\tau_j = \begin{cases} \sigma_A & \text{for } j = 0 \\ -\theta_j / \tau_0 & \text{for } j = 1, \ldots, q \end{cases}$$

and

$$f_j = \sum_{i=0}^{q-j} \tau_i \tau_{i+j} - \hat{\sigma}'(j) \qquad \text{for } j = 0, 1, \ldots, q$$

Then, the value of τ at the (i + 1)-th iteration is determined by the following:

$$\tau^{i+1} = \tau^i - \left(T^i\right)^{-1} f^i$$

The estimation procedure begins with the initial value

$$\tau^0 = (\sqrt{\hat{\sigma}'(0)}, \quad 0, \ldots, 0)^T$$

and terminates at iteration *i* when either ||*f* i|| is less than `relative_error` or *i* equals `max_iterations`. The moving average parameter estimates are obtained from the final estimate of τ by setting

$$\hat{\theta}_j = -\tau_j / \tau_0 \text{ for } j = 1, \ldots, q$$

The random shock variance is estimated by the following:

$$\hat{\sigma}_A^2 = \begin{cases} \hat{\sigma}(0) - \sum_{i=1}^{p} \hat{\phi}_i \hat{\sigma}(i) & \text{for } q = 0 \\ \tau_0^2 & \text{for } q \geq 0 \end{cases}$$

See Box and Jenkins (1976, pp. 498–500) for a description of a function that performs similar computations.

Least-squares Estimation

Suppose the time series {*Z*t} is generated by a nonseasonal ARMA model of the form,

$$\phi(B)\,(Z\text{t} - \mu) = \theta(B)A\text{t} \qquad \text{for t} \in \{0, \pm 1, \pm 2, \ldots\}$$

where *B* is the backward shift operator, μ is the mean of *Z*t, and

$$\phi(B) = 1 - \phi_1 B^{l_\phi(1)} - \phi_2 B^{l_\phi(2)} - \ldots - \phi_p B^{l_\phi(p)} \quad \text{for } p \geq 0$$
$$\theta(B) = 1 - \theta_1 B^{l_\theta(1)} - \theta_2 B^{l_\theta(2)} - \ldots - \theta_q B^{l_\theta(q)} \quad \text{for } q \geq 0$$

with *p* autoregressive and *q* moving average parameters. Without loss of generality, the following is assumed:

$$1 \leq l\text{f}\,(1) \leq l\text{f}\,(2) \leq \ldots \leq l\text{f}\,(p)$$

$$1 \leq l\text{q}\,(1) \leq l\text{q}\,(2) \leq \ldots \leq l\text{q}\,(q)$$

so that the nonseasonal ARMA model is of order (p', q'), where $p' = l\text{q}(p)$ and $q' = l\text{q}(q)$. Note that the usual hierarchical model assumes the following:

$$l\text{f}(i) = i,\ 1 \le i \le p$$

$$l\text{q}(j) = j,\ 1 \le j \le q$$

Consider the sum-of-squares function

$$S_T(\mu, \phi, \theta) = \sum_{-T+1}^{n} [A_t]^2$$

where

$$[A_t] = E\left[A_t \middle| (\mu, \phi, \theta, Z)\right]$$

and T is the backward origin. The random shocks {At} are assumed to be independent and identically distributed

$$N(0, \sigma_A^2)$$

random variables. Hence, the log-likelihood function is given by

$$l(\mu, \phi, \theta, \sigma_A) = f(\mu, \phi, \theta) - n\ln(\sigma_A) - \frac{S_T(\mu, \phi, \theta)}{2\sigma_A^2}$$

where $f(\mu, \phi, \theta)$ is a function of μ, ϕ, and θ.

For $T = 0$, the log-likelihood function is conditional on the past values of both Zt and At required to initialize the model. The method of selecting these initial values usually introduces transient bias into the model (Box and Jenkins 1976, pp. 210–211). For $T = \infty$, this dependency vanishes, and estimation problem concerns maximization of the unconditional log-likelihood function. Box and Jenkins (1976, p. 213) argue that

$$S_{\infty}(\mu,\phi,\theta)/\left(2\sigma_A^2\right)$$

dominates

$$l\left(\mu,\phi,\theta,\sigma_A^2\right)$$

The parameter estimates that minimize the sum-of-squares function are called least-squares estimates. For large *n*, the unconditional least-squares estimates are approximately equal to the maximum likelihood-estimates.

In practice, a finite value of *T* will enable sufficient approximation of the unconditional sum-of-squares function. The values of [*A*T] needed to compute the unconditional sum of squares are computed iteratively with initial values of *Z*t obtained by back forecasting. The residuals (including backcasts), estimate of random shock variance, and covariance matrix of the final parameter estimates also are computed. ARIMA parameters can be computed by using `imsls_f_difference` with `imsls_f_arma`.

Warning Errors

`IMSLS_LEAST_SQUARES_FAILED`	Least-squares estimation of the parameters has failed to converge. Increase “maxbc” and/or “tolerance” and/or “convergence_tolerance.” The estimates of the parameters at the last iteration may be used as new starting values.

Fatal Errors

`IMSLS_TOO_MANY_CALLS`	The number of calls to the function has exceeded "itmax"*(“n”+1) = %(i1). The user may try a new initial guess.
`IMSLS_INCREASE_ERRREL`	The bound for the relative error, “errrel” = %(r1), is too small. No further improvement in the approximate solution is possible. The user should increase "errrel".
`IMSLS_NEW_INITIAL_GUESS`	The iteration has not made good progress. The user may try a new initial guess.

max_arma

Exact maximum likelihood estimation of the parameters in a univariate ARMA (autoregressive, moving average) time series model.

Synopsis

float *imsls_f_max_arma (*int* n_obs, *float* w[], *int* p, *int* q,…,0)

The type *double* function is imsls_d_max_arma.

Required Arguments

int n_obs (Input)
Number of observations in the time series.

float w[] (Input)
Array of length n_obs containing the time series.

int p (Input)
Non-negative number of autoregressive parameters.

int q (Input)
Non-negative number of moving average parameters.

Return Value

Pointer to an array of length 1+p+q with the estimated constant, AR and MA parameters. If no value can be computed, NULL is returned.

Synopsis with Optional Arguments

```
float *imsls_f_max_arma (int n_obs, float w[], int p, int q,
  IMSLS_INITIAL_ESTIMATES, float init_ar[] float init_ma[],
  IMSLS_PRINT_LEVEL, int iprint,
  IMSLS_MAX_ITERATIONS, int maxit,
  IMSLS_LOG_LIKELIHOOD, float *log_likeli,
  IMSLS_VAR_NOISE, float *avar,
  IMSLS_ARMA_INFO, Imsls_f_arma **arma_info,
  IMSLS_MEAN_ESTIMATE, float *w_mean,
```

IMSLS_RETURN_USER, *float* *constant, *float* ar[], *float* ma[],
0)

Optional Arguments

IMSLS_INITIAL_ESTIMATES, *float* init_ar[], *float* init_ma[] (Input)

If specified, init_ar is an array of length p containing preliminary estimates of the autoregressive parameters, and init_ma is an array of length q containing preliminary estimates of the moving average parameters; otherwise, they are computed internally. If p=0 or q=0, then the corresponding arguments are ignored.

IMSLS_PRINT_LEVEL, *int* iprint (Input)

Printing option:

0 — No printing.

1 — Prints final results only.

2 — Prints intermediate and final results.

Default: iprint = 0

IMSLS_MAX_ITERATIONS, *int* maxit (Input)

Maximum number of estimation iterations.

Default: maxit = 300

IMSLS_VAR_NOISE, *float* *avar (Output)

Estimate of innovation variance.

IMSLS_LOG_LIKELIHOOD, *float* *log_likeli (Output)

Value of -2*(ln(likelihood)) for the fitted model.

IMSLS_ARMA_INFO, *Imsls_f_arma* **arma_info (Output)

Address of a pointer to an internally allocated structure of type *Imsls_f_arma* that contains information necessary in the call to imsls_f_arma_forecast.

IMSLS_MEAN_ESTIMATE, *float* *w_mean (Input/Output)

Estimate of the mean of the time series w. On return, w_mean contains an update of the mean.

Default: Time series w is centered about its sample mean.

IMSLS_RETURN_USER, *float* *constant, *float* ar[], *float* ma[] (Output)

If specified, constant is the constant parameter estimate, ar is an array of length p containing the final autoregressive parameter estimates, and ma is an array of length q containing the final moving average parameter estimates.

Description

The function imsls_f_max_arma is derived from the maximum likelihood estimation algorithm described by Akaike, Kitagawa, Arahata and Tada (1979), and the XSARMA routine published in the TIMSAC-78 Library.

Using the notation developed in the Time Domain Methodology at the beginning of this chapter, the stationary time series W_t with mean μ can be represented by the nonseasonal autoregressive moving average (ARMA) model by the following relationship:

$$\phi(B)(W_t - \mu) = \theta(B)a_t$$

where

$$t \in ZZ = \{\cdots, -2, -1, 0, 1, 2, \cdots\},$$

B is the backward shift operator defined by $B^k W_t = W_{t-k}$,

$$\phi(B) = 1 - \phi_1 B - \phi_2 B^2 - \cdots - \phi_p B^p, \quad p \geq 0,$$

and

$$\theta(B) = 1 - \theta_1 B - \theta_2 B^2 - \cdots - \theta_q B^q, \quad q \geq 0.$$

Function imsls_f_max_arma estimates the AR coefficients $\phi_1, \phi_2, \cdots, \phi_p$ and the MA coefficients $\theta_1, \theta_2, \cdots, \theta_q$ using maximum likelihood estimation.

Function imsls_f_max_arma checks the initial estimates for both the autoregressive and moving average coefficients to ensure that they represent a stationary and invertible series respectively.

If

$$\phi_1, \phi_2, \cdots, \phi_p$$

are the initial estimates for a stationary series then all (complex) roots of the following polynomial will fall outside the unit circle:

$$1 - \phi_1 z - \phi_2 z^2 - \cdots - \phi_p z^p .$$

If

$$\theta_1, \theta_2, \cdots, \theta_q$$

are initial estimates for an invertible series then all (complex) roots of the polynomial

$$1 - \theta_1 z - \theta_2 z^2 - \cdots - \theta_q z^q$$

will fall outside the unit circle.

Initial values for the AR and MA coefficients can be supplied by vectors `init_ar` and `init_ma`. Otherwise, estimates are computed internally by the method of moments. `imsls_f_max_arma` computes the roots of the associated polynomials. If the AR estimates represent a non-stationary series, `imsls_f_max_arma` issues a warning message and replaces `init_ar` with initial values that are stationary. If the MA estimates represent a non-invertible series, `imsls_f_max_arma` issues a terminal error, and new initial values have to be sought.

`imsls_f_max_arma` also validates the final estimates of the AR coefficients to ensure that they too represent a stationary series. This is done to guard against the possibility that the internal log-likelihood optimizer converged to a non-stationary solution. If non-stationary estimates are encountered, `imsls_f_max_arma` issues a fatal error message.

For model selection, the ARMA model with the minimum value for *AIC* might be preferred,

$$AIC = \texttt{log\_likeli} + 2(\texttt{p}+\texttt{q})$$

Function imsls_f_max_arma can also handle white noise processes, i.e. ARMA(0,0) Processes.

auto_uni_ar

Automatic selection and fitting of a univariate autoregressive time series model. The lag for the model is automatically selected using Akaike's information criterion (AIC). Estimates of the autoregressive parameters for the model with minimum AIC are calculated using method of moments, method of least squares, or maximum likelihood.

Synopsis

float *imsls_f_auto_uni_ar (*int* n_obs, *float* z[], *int* maxlag, *int* *p,...,0)

The type *double* function is imsls_d_auto_uni_ar.

Required Arguments

int n_obs (Input)
Number of observations in the time series.

float z[] (Input)
Array of length n_obs containing the stationary time series.

int maxlag (Input)
Maximum number of autoregressive parameters requested. It is required that $1 \le$ maxlag $\le$ n_obs/2.

int *p (Output)
Number of autoregressive parameters in the model with minimum AIC.

Return Value

Vector of length 1+ maxlag containing the estimates for the constant and the autoregressive parameters in the model with minimum AIC. The estimates are located in the first 1+ p locations of this array.

Synopsis with Optional Arguments

```
float   *imsls_f_auto_uni_ar (int n_obs, float z[], int maxlag, int *p,
        IMSLS_PRINT_LEVEL, int iprint,
        IMSLS_MAX_ITERATIONS, int maxit,
        IMSLS_METHOD, int method,
        IMSLS_VAR_NOISE, float *avar,
        IMSLS_AIC, float *aic,
        IMSLS_MEAN_ESTIMATE, float *z_mean,
        IMSLS_RETURN_USER, float *constant, float ar[],
        0)
```

Optional Arguments

IMSLS_PRINT_LEVEL, *int* iprint (Input)

Printing option:

0 — No printing.

1 — Prints final results only.

2 — Prints intermediate and final results.

Default: iprint = 0

IMSLS_MAX_ITERATIONS, *int* maxit (Input)

Maximum number of estimation iterations.

Default: maxit = 300

IMSLS_METHOD, *int* method (Input)

Estimation method option:

0 — Method of moments

1 — Method of least squares realized through Householder transformations

2 — Maximum likelihood

Default: method = 1

IMSLS_VAR_NOISE, *float* *avar (Output)

Estimate of innovation variance.

IMSLS_AIC, *float* *aic (Output)

Minimum AIC.

IMSLS_MEAN_ESTIMATE, *float* *z_mean (Input/Output)

Estimate of the mean of the time series z. On return, z_mean contains an update of the mean. Default: Time series z is centered about its sample mean.

IMSLS_RETURN_USER, *float* *constant, *float* ar[] (Output)

If specified, constant is the constant parameter estimate, ar is an array of length maxlag containing the final autoregressive parameter estimates in its first p locations.

Description

Function auto_uni_ar automatically selects the order of the AR model that best fits the data and then computes the AR coefficients. The algorithm used in auto_uni_ar is derived from the work of Akaike, H., et. al (1979) and Kitagawa and Akaike (1978). This code was adapted from the UNIMAR procedure published as part of the TIMSAC-78 Library.

The best fit AR model is determined by successively fitting AR models with 0, 1, 2, ..., maxlag autoregressive coefficients. For each model, Akaike's Information Criterion (AIC) is calculated based on the formula

$$AIC = -2\ln(likelihood) + 2(\mathrm{p}+1)$$

Function auto_uni_ar uses the approximation to this formula developed by Ozaki and Oda (1979),

$$AIC = (\mathrm{n\_obs} - \mathrm{maxlag})\ln(\hat{\sigma}^2) + 2(\mathrm{p}+1) + (\mathrm{n\_obs} - \mathrm{maxlag})(\ln(2\pi)+1),$$

where $\hat{\sigma}^2$ is an estimate of the residual variance of the series, commonly known in time series analysis as the innovation variance. By dropping the constant

$$(\mathrm{n\_obs} - \mathrm{maxlag})(\ln(2\pi)+1),$$

the calculation is simplified to

$$AIC = (\mathrm{n\_obs} - \mathrm{maxlag})\ln(\hat{\sigma}^2) + 2(\mathrm{p}+1)$$

The best fit model is the model with minimum AIC. If the number of parameters in this model is equal to the highest order autoregressive model fitted, i.e., p=`maxlag`, then a model with smaller AIC might exist for larger values of `maxlag`. In this case, increasing `maxlag` to explore AR models with additional autoregressive parameters might be warranted.

If `method` = 0, estimates of the autoregressive coefficients for the model with minimum AIC are calculated using method of moments. If `method` =1, the coefficients are determined by the method of least squares applied in the form described by Kitagawa and Akaike (1978). Otherwise, if `method` =2, the coefficients are estimated using maximum likelihood.

ts_outlier_identification

Detects and determines outliers and simultaneously estimates the model parameters in a time series whose underlying outlier free series follows a general seasonal or nonseasonal ARMA model.

Synopsis

float `*imsls_f_ts_outlier_identification` (*int* `n_obs`, *int* `model[]`,
float `w[]`,...,0)

The type *double* function is `imsls_d_ts_outlier_identification`.

Required Arguments

int `n_obs` (Input)
Number of observations in the time series.

int `model[]` (Input)
Vector of length 4 containing the numbers *p*, *q*, *s*, *d* of the ARIMA $(p,0,q)\times(0,d,0)_s$ model the outlier free series is following.

float w`[]` (Input)
An array of length `n_obs` containing the time series.

Return Value

Pointer to an array of length `n_obs` containing the outlier free time series.
If an error occurred, `NULL` is returned.

Synopsis with Optional Arguments

```
float  *imsls_f_ts_outlier_identification (int n_obs,
        int model[], float w[],
        IMSLS_RETURN_USER, float x[],
        IMSLS_DELTA, float delta,
        IMSLS_CRITICAL, float critical,
        IMSLS_EPSILON, float epsilon,
        IMSLS_RELATIVE_ERROR, float relative_error,
        IMSLS_RESIDUAL, float **residual,
        IMSLS_RESIDUAL_USER, float residual[],
        IMSLS_RESIDUAL_SIGMA, float *res_sigma,
        IMSLS_NUM_OUTLIERS, int *num_outliers,
        IMSLS_OUTLIER_STATISTICS, int **outlier_stat,
        IMSLS_OUTLIER_STATISTICS_USER, int outlier_stat[],
        IMSLS_TAU_STATISTICS, float **tau_stat,
        IMSLS_TAU_STATISTICS_USER, float tau_stat[],
        IMSLS_OMEGA_WEIGHTS, float **omega,
        IMSLS_OMEGA_WEIGHTS_USER, float omega[],
        IMSLS_ARMA_PARAM, float **parameters,
        IMSLS_ARMA_PARAM_USER, float parameters[],
        IMSLS_AIC, float *aic,
        0)
```

Optional Arguments

`IMSLS_RETURN_USER`, *float* `x[]` (Output)
A user supplied array of length `n_obs` containing the outlier free series.

`IMSLS_DELTA`, *float* `delta` (Input)
The dampening effect parameter used in the detection of a Temporary Change Outlier (TC), 0<`delta` < 1.
Default: `delta` = 0.7

IMSLS_CRITICAL, *float* critical (Input)

Critical value used as a threshold for outlier detection, critical > 0.

Default: critical = 3.0

IMSLS_EPSILON, *float* epsilon (Input)

Positive tolerance value controlling the accuracy of parameter estimates during outlier detection.

Default: epsilon = 0.001

IMSLS_RELATIVE_ERROR, *float* relative_error (Input)

Stopping criterion for the nonlinear equation solver used in function imsls_f_arma.

Default: relative_error = 10^{-10}.

IMSLS_RESIDUAL, *float* **residual (Output)

Address of a pointer to an internally allocated array of length n_obs containing the residuals for the outlier free series.

IMSLS_RESIDUAL_USER, *float* residual[] (Output)

Storage for array residual is provided by the user. See IMSLS_RESIDUAL.

IMSLS_RESIDUAL_SIGMA, *float* *res_sigma (Output)

Residual standard error of the outlier free series.

IMSLS_NUM_OUTLIERS, *int* *num_outliers (Output)

The number of outliers detected.

IMSLS_OUTLIER_STATISTICS, *int* **outlier_stat (Output)

Address of a pointer to an internally allocated array of length num_outliers × 2 containing outlier statistics. The first column contains the time at which the outlier was observed (t=1,2,...,n_obs) and the second column contains an identifier indicating the type of outlier observed.

Outlier types fall into one of five categories:

0 Innovational Outliers (IO)

1 Additive outliers (AO)

2 Level Shift Outliers (LS)

3 Temporary Change Outliers (TC)

4 Unable to Identify (UI).

Use `IMSLS_NUM_OUTLIERS` to obtain `IMSLS_NUM_OUTLIERS`, the number of detected outliers. If `num_outliers` = 0, `NULL` is returned.

`IMSLS_OUTLIER_STATISTICS_USER`, *int* `outlier_stat[]` (Output)

A user allocated array of length `n_obs` × 2 containing outlier statistics in the first `num_outliers` locations. See `IMSLS_OUTLIER_STATISTICS`.
If `num_outliers` = 0, `outlier_stat` stays unchanged.

`IMSLS_TAU_STATISTICS`, *float* `**tau_stat` (Output)

Address of a pointer to an internally allocated array of length `num_outliers` containing the *t* value for each detected outlier.
If `num_outliers` = 0, `NULL` is returned.

`IMSLS_TAU_STATISTICS_USER`, *float* `tau_stat[]` (Output)

A user allocated array of length `n_obs` containing the *t* value for each detected outlier in its first `num_outliers` locations.
If `num_outliers` = 0, `tau_stat` stays unchanged.

`IMSLS_OMEGA_WEIGHTS`, *float* `**omega` (Output)

Address of a pointer to an internally allocated array of length `num_outliers` containing the computed ω weights for the detected outliers.
If `num_outliers` = 0, `NULL` is returned.

`IMSLS_OMEGA_WEIGHTS_USER` *float* `omega[]` (Output)

A user allocated array of length `n_obs` containing the computed ω weights for the detected outliers in its first `num_outliers` locations.
If `num_outliers` = 0, `omega` stays unchanged.

`IMSLS_ARMA_PARAM`, *float* `**parameters` (Output)

Address of a pointer to an internally allocated array of length 1+*p*+*q* containing the estimated constant, AR and MA parameters.

IMSLS_ARMA_PARAM_USER *float* parameters[] (Output)

A user allocated array of length 1+*p*+*q* containing the estimated constant, AR and MA parameters.

IMSLS_AIC, *float* *aic (Output)

Akaike's information criterion (AIC).

Description

Consider a univariate time series $\{Y_t\}$ that can be described by the following multiplicative seasonal ARIMA model of order $(p,0,q)\times(0,d,0)_s$:

$$Y_t - \mu = \frac{\theta(B)}{\Delta_s^d \phi(B)} a_t,\ t = 1,\ldots,n.$$

Here, $\Delta_s^d = (1-B^s)^d$, $\theta(B) = 1-\theta_1 B-\ldots-\theta_q B^q$, $\phi(B) = 1-\phi_1 B-\ldots-\phi_p B^p$. B is the lag operator, $B^k Y_t = Y_{t-k}$, $\{a_t\}$ is a white noise process, and μ denotes the mean of the series $\{Y_t\}$.

In general, $\{Y_t\}$ is not directly observable due to the influence of outliers. Chen and Liu (1993) distinguish between four types of outliers: innovational outliers (IO), additive outliers (AO), temporary changes (TC) and level shifts (LS). If an outlier occurs as the last observation of the series, then Chen and Liu's algorithm is unable to determine the outlier's classification. In imsls_f_ts_outlier_identification, such an outlier is called a UI (unable to identify) and is treated as an innovational outlier.

In order to take the effects of multiple outliers occurring at time points $t_1, t_2, \ldots, t_m$ into account, Chen and Liu consider the following model:

$$Y_t^* - \mu = \sum_{j=1}^{m} \omega_j L_j(B) I_t(t_j) + \frac{\theta(B)}{\Delta_s^d \phi(B)} a_t .$$

Here, $\{Y_t^*\}$ is the observed outlier contaminated series, and ω_j and $L_j(B)$ denote the magnitude and dynamic pattern of outlier j, respectively. $I_t(t_j)$ is an indicator function that determines the temporal

course of the outlier effect, $I_{t_j}(t_j) = 1$, $I_t(t_j) = 0$ otherwise. **Note** that $L_j(B)$ operates on I_t via $B^k I_t = I_{t-k}, k = 0,1,\ldots$.

The last formula shows that the outlier free series $\{Y_t\}$ can be obtained from the original series $\{Y_t^*\}$ by removing all occurring outlier effects:

$$Y_t = Y_t^* - \sum_{j=1}^{m} \omega_j L_j(B) I_t(t_j) .$$

The different types of outliers are charaterized by different values for $L_j(B)$:

1. $L_j(B) = \dfrac{\theta(B)}{\Delta_s^d \phi(B)}$ for an innovational outlier,

2. $L_j(B) = 1$ for an additive outlier,

3. $L_j(B) = (1-B)^{-1}$ for a level shift outlier *and*

4. $L_j(B) = (1-\delta B)^{-1}, 0 < \delta < 1,$ for a temporary change outlier.

Function `imsls_f_ts_outlier_identification` is an implementation of Chen and Liu's algorithm. It determines the coefficients in $\phi(B), \theta(B)$ and the outlier effects in the model for the observed series jointly in three stages. The magnitude of the outlier effects is determined by least squares estimates. Outlier detection itself is realized by examination of the maximum value of the standardized statistics of the outlier effects. For a detailed description, see Chen and Liu's original paper (1993).

Intermediate and final estimates for the coefficients in $\phi(B)$ and $\theta(B)$ are computed by functions `imsls_f_arma` and `imsls_f_max_arma`. If the roots of $\phi(B)$ or $\theta(B)$ lie on or within the unit circle, then the algorithm stops with an appropriate error message. In this case, different values for *p* and *q* should be tried.

auto_arima

Automatically identifies time series outliers, determines parameters of a multiplicative seasonal ARIMA $(p,0,q)\times(0,d,0)_s$ model and produces forecasts that incorporate the effects of outliers whose effects persist beyond the end of the series.

Synopsis

float `*imsls_f_auto_arima` (*int* `n_obs`, *int* `tpoints[]`, *float* `x[]`,...,0)

The type *double* function is `imsls_d_auto_arima`.

Required Arguments

int `n_obs` (Input)

Number of observations in the original time series. Assuming that the series is defined at time points $t_1,\ldots,t_{\texttt{n\_obs}}$, the actual length of the series, including missing observations is $n = t_{\texttt{n\_obs}} - t_1 + 1$.

int `tpoints[]` (Input)

A vector of length `n_obs` containing the time points $t_1, t_2, \ldots t_{n\_obs}$ the time series was observed. It is required that $t_1, t_2, \ldots t_{n\_obs}$ are in strictly ascending order.

float `x[]` (Input)

A vector of length `n_obs` containing the observed time series values $Y_1^*, Y_2^*, \cdots, Y_{n\_obs}^*$. This series can contain outliers and missing observations. Outliers are identified by this routine and missing values are identified by the time values in vector `tpoints`. If the time interval between two consecutive time points is greater than one, i.e. $t_{i+1} - t_i = m > 1$, then $m-1$ missing values are assumed to exist between t_i and t_{i+1} at times $t_i + 1, t_i + 2, \ldots, t_{i+1} - 1$. Therefore, the gap free series is assumed to be defined for equidistant time points . Missing values are automatically estimated prior to identifying outliers and producing forecasts. Forecasts are generated for both missing and observed values.

Return Value

Pointer to an array of length 1 + *p* + *q* with the estimated constant, AR and MA parameters used to fit the outlier-free series using an ARIMA $(p,0,q)\times(0,d,0)_s$ model. Upon completion, if *d*=`model[3]`=0, then an ARMA(*p, q*) model or AR(*p*) model is fitted to the outlier-free version of the observed series Y_t^*. If *d*=`model[3]`>0, these parameters are computed for an ARMA(*p*,*q*) representation of the seasonally adjusted series $Z_t^* = \Delta_s^d \cdot Y_t^* = (1-B_s)^d \cdot Y_t^*$, where $B_s Y_t^* = Y_{t-s}^*$ and *s*=`model[2]`≥1.
If an error occurred, `NULL` is returned.

Synopsis with Optional Arguments

```
float  *imsls_f_auto_arima (int n_obs, int tpoints[], float x[],
         IMSLS_METHOD, int method,
         IMSLS_MAX_LAG, int maxlag,
         IMSLS_MODEL, int model[],

         IMSLS_OUTLIER_FORECAST_USER, float outlier_forecast[],
         0)
```

Optional Arguments

`IMSLS_METHOD`, *int* `method` (Input)

The method used in model selection:

1 — Automatic ARIMA $(p,0,0)\times(0,d,0)_s$ selection

3 — Specified ARIMA $(p,0,q)\times(0,d,0)_s$ model

Requires argument `IMSLS_MODEL`.

Default: `method` = 1

`IMSLS_MAX_LAG`, *int* `maxlag` (Input)

The maximum lag allowed when fitting an AR(*p*) model.

Default: `maxlag` = 10

`IMSLS_MODEL`, *int* `model[]` (Input/Output)

Array of length 4 containing the values for *p, q, s, d*. If `method`=3 is chosen, then the values for *p* and *q* must be defined. If `IMSLS_S_INITIAL` and `IMSLS_D_INITIAL` are not defined, then also *s* and *d* must be given. If `method`=1, then model is ignored as an input array. On output, model contains the optimum values for *p, q, s, d* in model[0], model[1] and model[3], respectively.

`IMSLS_DELTA`, *float* `delta` (Input)

The dampening effect parameter used in the detection of a Temporary Change Outlier (TC), 0<`delta`<1.

Default: `delta` = 0.7

`IMSLS_CRITICAL`, *float* `critical` (Input)

Critical value used as a threshold for outlier detection, `critical` > 0.

Default: `critical` = 3.0

`IMSLS_EPSILON`, *float* `epsilon` (Input)

Positive tolerance value controlling the accuracy of parameter estimates during outlier detection.

Default: `epsilon` = 0.001

`IMSLS_RESIDUAL_USER`, *float* `residual[]` (Output)

Storage for array `residual` is provided by the user.

`IMSLS_RESIDUAL_SIGMA`, *float* `*res_sigma` (Output)

Residual standard error (RSE) of the outlier free original series.

`IMSLS_NUM_OUTLIERS`, *int* `*num_outliers` (Output)

The number of outliers detected.

IMSLS_P_INITIAL, *int* n_p_initial, *int* p_initial[] (Input)

An array with n_p_initial elements containing the candidate values for *p*, from which the optimum is being selected. All candidate values in p_initial[] must be non-negative and n_p_initial ≥ 1. If method=2, then IMSLS_P_INITIAL must be defined. Otherwise, n_p_initial and p_initial are ignored.

IMSLS_Q_INITIAL, *int* n_q_initial, *int* q_initial[] (Input)

An array with n_q_initial elements containing the candidate values for *q*, from which the optimum is being selected. All candidate values in q_initial[] must be non-negative and n_q_initial ≥ 1. If method=2, then IMSLS_Q_INITIAL must be defined. Otherwise, n_q_initial and q_initial are ignored.

IMSLS_S_INITIAL, *int* n_s_initial, *int* s_initial[] (Input)

A vector of length n_s_initial containing the candidate values for s, from which the optimum is being selected. All candidate values in s_initial[] must be positive and n_s_initial ≥ 1.

Default: n_s_initial=1, s_initial={1}

IMSLS_D_INITIAL, *int* n_d_initial, *int* d_initial[] (Input)

A vector of length n_d_initial containing the candidate values for *d*, from which the optimum is being selected. All candidate values in d_initial[] must be non-negative and n_d_initial ≥ 1.

Default: n_d_initial=1, d_initial={0}

IMSLS_OUTLIER_STATISTICS, *int* **outlier_stat (Output)

Address of a pointer to an internally allocated array of length num_outliers by 2 containing outlier statistics. The first column contains the time at which the outlier was observed ($t = t_1, t_1 + 1, t_1 + 2, \ldots, t_{n\_obs}$) and the second column contains an identifier indicating the type of outlier observed. Outlier types fall into one of five categories:

0 Innovational Outliers (IO)

1 Additive Outliers (AO)

2 Level Shift Outliers (LS)

3 Temporary Change Outliers (TC)

4 Unable to Identify (UI).

If `num_outliers=0`, `NULL` is returned.

`IMSLS_OUTLIER_STATISTICS_USER`, *int* `outlier_stat[]` (Output)

A user allocated array of length $n \times 2$ containing outlier statistics in its first `num_outliers` rows. Here, $n = t_{n\_obs} - t_1 + 1 \geq$ `n_obs`.

If `num_outliers` = 0, `outlier_stat` stays unchanged.

`IMSLS_AIC`, *float* `*aic` (Output)

The AIC (Akaike's Information Criterion) value for the optimum model. Uses an approximation of the maximum log-likelihood based on an estimate of the innovation variance of the series.

`IMSLS_AICC`, *float* `*aicc` (Output)

The AICC (corrected AIC) value for the optimum model. Uses an approximation of the maximum log-likelihood based on an estimate of the innovation variance of the series.

`IMSLS_BIC`, *float* `*bic` (Output)

The BIC (Bayesian Information Criterion) value for the optimum model. Uses an approximation of the maximum log-likelihood based on an estimate of the innovation variance of the series.

`IMSLS_MODEL_SELECTION_CRITERION`, *int* `criterion` (Input)

The information criterion used for optimum model selection.

criterion	selected information criterion
0	Akaike's Information Criterion (AIC)
1	Akaike's Corrected Information Criterion (AICC)
2	Bayesian Information Criterion (BIC)

Default: criterion = 0.

IMSLS_OUT_FREE_SERIES_USER, *float* outfree_series[] (Output)

A user allocated array of length *n* by 2, where $n = t_{n\ obs} - t_1 + 1$.

IMSLS_CONFIDENCE, *float* confidence (Input)

Confidence level for computing forecast confidence limits, taken from the exclusive interval (0, 100). Typical choices for confidence are 90.0, 95.0 and 99.0.

Default: confidence = 95.0

IMSLS_NUM_PREDICT, *int* n_predict (Input)

The number of forecasts requested. Forecasts are made at origin $t_{n\ obs}$, i.e. from the last observed value of the series.

Default: n_predict = 0

IMSLS_OUTLIER_FORECAST, *float* **outlier_forecast (Output)

Address of a pointer to an internally allocated array of length n_predict by 3. The first column contains the forecasted values for the original series for *t*= $t_{n\ obs}$ +1, $t_{n\ obs}$ +2,..., $t_{n\ obs}$ +n_predict. The second column contains standard errors for these forecasts, and the third column contains the ψ weights of the infinite order moving average form of the model.

IMSLS_OUTLIER_FORECAST_USER, *float* outlier_forecast[] (Output)

A user allocated array of length n_predict by 3.

IMSLS_RETURN_USER, *float* x[] (Output)

A user allocated array containing the estimated constant, AR and MA parameters in its first 1+*p*+*q* locations. The values *p* and *q* can be estimated by upper bounds: If method=1, an upper bound for *p* would be maxlag, and *q*= 0. If method=2, upper bounds for *p* and *q* would be the maximum values in arrays p_initial and q_initial, respectively. If method=3, *p*= model[0] and *q*= model[1].

Description

Function imsls_f_auto_arima determines the parameters of a multiplicative seasonal ARIMA $(p,0,q)\times(0,d,0)_s$ model, and then uses the fitted model to identify outliers and prepare

forecasts. The order of this model can be specified or automatically determined.
The ARIMA $(p,0,q)\times(0,d,0)_s$ model handled by `imsls_f_auto_arima` has the following form:

$$\phi(B)\Delta_s^d(Y_t-\mu)=\theta(B)a_t,\quad t=1,2,\ldots,n,$$

where

$$\phi(B)=1-\phi_1B-\phi_2B^2-\cdots-\phi_pB^p,\ \ \theta(B)=1-\theta_1B-\theta_2B^2-\cdots-\theta_qB^q,\ \ \Delta_s^d=(1-B^s)^d$$

and

$$B^kY_t=Y_{t-k}.$$

It is assumed that all roots of $\phi(B)$ and $\theta(B)$ lie outside the unit circle. Clearly, if $s=1$ this reduces to the traditional ARIMA(*p, d, q*) model.

Y_t is the unobserved, outlier-free time series with mean μ, and white noise a_t. This model is referred to as the underlying, outlier-free model. Function `imsls_f_auto_arima` does not assume that this series is observable. It assumes that the observed values might be contaminated by one or more outliers, whose effects are added to the underlying outlier-free series:

$$Y_t^*=Y_t+outlier\_effect_t.$$

Outlier identification uses the algorithm developed by Chen and Liu (1993). Outliers are classified into 1 of 5 types:

1. innovational
2. additive
3. level shift
4. temporary change *and*
5. unable to identify

Once outliers are identified, `imsls_f_auto_arima` estimates Y_t, the outlier-free series representation of the data, by removing the estimated outlier effects.

Using the information about the adjusted ARIMA $(p,0,q)\times(0,d,0)_s$ model and the removed outliers, forecasts are then prepared for the outlier-free series. Outlier effects are added to these forecasts to produce a forecast for the observed series, Y_t^*. If there are no outliers, then the forecasts for the outlier-free series and the observed series will be identical.

Model Selection

Users have an option of either specifying specific values for *p, q , s* and *d* or have `imsls_f_auto_arima` automatically select best fit values. Model selection can be conducted in one of three methods listed below depending upon the value of variable `method`.

Method 1: Automatic ARIMA $(p,0,0)\times(0,d,0)_s$ *Selection*

This method initially searches for the AR(p) representation with minimum AIC for the noisy data, where *p* =0,...,`maxlag`.

If `IMSLS_D_INITIAL` is defined then the values in `s_initial` and `d_initial` are included in the search to find an optimum ARIMA $(p,0,0)\times(0,d,0)_s$ representation of the series. Here, every possible combination of values for *p, s* in `s_initial` and *d* in `d_initial` is examined. The best found ARIMA $(p,0,0)\times(0,d,0)_s$ representation is then used as input for the outlier detection routine.

The optimum values for *p, q, s* and *d* are returned in `model[0]`, `model[1]`, `model[2]` and `model[3]`, respectively.

Method 3: Specified ARIMA $(p,0,q)\times(0,d,0)_s$ *Model*

In the third method, specific values for *p*, *q*, *s* and *d* are given. The values for *p* and *q* must be defined in `model[0]` and `model[1]`, respectively. If `IMSLS_S_INITIAL` and `IMSLS_D_INITIAL` are not defined, then values $s>0$ and $d\geq 0$ must be specified in `model[2]` and `model[3]`. If `IMSLS_S_INITIAL` and `IMSLS_D_INITIAL` are defined, then a grid search for the optimum values of *s* and *d* is conducted using all possible combinations of input values in `s_initial` and `d_initial`. The optimum values of *s* and *d* can be found in `model[2]` and `model[3]`, respectively.

Outliers

The algorithm of Chen and Liu (1993) is used to identify outliers. The number of outliers identified is returned in `num_outliers`. Both the time and classification for these outliers are returned in `outlier_stat[]`. Outliers are classified into one of five categories based upon the standardized statistic for each outlier type. The time at which the outlier occurred is given in the first column of `outlier_stat`. The outlier identifier returned in the second column is according to the descriptions in the following table:

Outlier Identifier	Name	General Description
0	(IO) Innovational Outlier	Innovational outliers persist. That is, there is an initial impact at the time the outlier occurs. This effect continues in a lagged fashion with all future observations. The lag coefficients are determined by the coefficient of the underlying ARIMA $(p,0,q)\times(0,d,0)_s$ model.
1	(AO) Additive Outlier	Additive outliers do not persist. As the name implies, an additive outlier effects only the observation at the time the outlier occurs. Hence additive outliers have no effect on future forecasts.
2	(LS) Level Shift	Level shift outliers persist. They have the effect of either raising or lowering the mean of the series starting at the time the outlier occurs. This shift in the mean is abrupt and permanent.
3	(TC) Temporary Change	Temporary change outliers persist and are similar to level shift outliers with one major exception. Like level shift outliers, there is an abrupt change in the mean of the series at the time this outlier occurs. However, unlike level shift outliers, this shift is not permanent. The TC outlier gradually decays, eventually bringing the mean of the series back to its original value. The rate of this decay is modeled using the parameter `delta`. The default of `delta=` 0.7 is the value recommended for general use by Chen and Liu (1993).
4	(UI)	If an outlier is identified as the last observation, then the algorithm is unable to determine the outlier's

	Unable to Identify	classification. For forecasting, a UI outlier is treated as an IO outlier. That is, its effect is lagged into the forecasts.

Except for additive outliers (AO), the effect of an outlier persists to observations following that outlier. Forecasts produced by `imsls_f_auto_arima` take this into account.

difference

Differences a seasonal or nonseasonal time series.

Synopsis

float `*imsls_f_difference` (*int* `n_observations`, *float* `z[]`, *int* `n_differences`, *int* `periods[]`, ..., 0)

The type *double* function is `imsls_d_difference`.

Required Arguments

int `n_observations` (Input)
Number of observations.

float `z[]` (Input)
Array of length `n_observations` containing the time series.

int `n_differences` (Input)
Number of differences to perform. Argument `n_differences` must be greater than or equal to 1.

int `periods[]` (Input)
Array of length `n_differences` containing the periods at which `z` is to be differenced.

Return Value

Pointer to an array of length `n_observations` containing the differenced series.

Synopsis with Optional Arguments

float *imsls_f_difference (*int* n_observations, *float* z[], *int* n_differences, *int* periods[],
IMSLS_ORDERS, *int* orders[],
IMSLS_LOST, *int*v*n_lost,
IMSLS_EXCLUDE_FIRST, *or*
IMSLS_SET_FIRST_TO_NAN,
IMSLS_RETURN_USER, *float* w[],
0)

Optional Arguments

IMSLS_ORDERS, *int* orders[] (Input)

Array of length n_differences containing the order of each difference given in periods. The elements of orders must be greater than or equal to 0.

IMSLS_LOST, *int* *n_lost (Output)

Number of observations lost because of differencing the time series z.

IMSLS_EXCLUDE_FIRST, *or*

IMSLS_SET_FIRST_TO_NAN

If IMSLS_EXCLUDE_FIRST is specified, the first n_lost are excluded from w due to differencing. The differenced series w is of length n_observations − n_lost. If IMSLS_SET_FIRST_TO_NAN is specified, the first n_lost observations are set to NaN (Not a Number). This is the default if neither IMSLS_EXCLUDE_FIRST nor IMSLS_SET_FIRST_TO_NAN is specified.

IMSLS_RETURN_USER, *float* w[] (Output)

If specified, w contains the differenced series. If IMSLS_EXCLUDE_FIRST also is specified, w is of length n_observations. If IMSLS_SET_FIRST_TO_NAN is specified or neither IMSLS_EXCLUDE_FIRST nor IMSLS_SET_FIRST_TO_NAN is specified, w is of length n_observations − n_lost.

Description

Function imsls_f_difference performs *m* = n_differences successive backward differences of period *s*i = periods [*i* − 1] and order di = orders [*i* − 1] for *i* = 1, ..., *m* on the *n* = n_observations observations {*Z*t} for *t* = 1, 2, ..., *n*.

Consider the backward shift operator *B* given by

$$B^k Z_t = Z_{t-k}$$

for all *k*. Then, the *backward difference operator* with period *s* is defined by the following:

$$\Delta_s Z_t = (1 - B^s) Z_t = Z_t - Z_{t-s} \quad \text{for} \quad s > 0 .$$

Note that $B^s Z_t$ and $\Delta^s Z_t$ are defined only for *t* = (*s* + 1), ..., *n*. Repeated differencing with period *s* is simply

$$\Delta_s^d Z_t = \left(1 - B^s\right)^d Z_t = \sum_{j=0}^{d} \frac{d!}{j!(d-j)!} (-1)^j B^{sj} Z_t$$

where $d \geq 0$ is the order of differencing. Note that

$$\Delta_s^d Z_t$$

is defined only for *t* = (*sd* + 1), ..., *n*.

The general difference formula used in the function `imsls_f_difference` is given by

$$W_t = \begin{cases} \text{NaN} & \text{for } t = 1, \ldots, n_L \\ \Delta_{s_1}^{d_1} \Delta_{s_2}^{d_2} \ldots \Delta_{s_m}^{d_m} Z_t & \text{for } t = n_L + 1, \ldots, n \end{cases}$$

where $n\mathrm{L}$ represents the number of observations "lost" because of differencing and NaN represents the missing value code. Note that

$$n_L = \sum_j s_j d_j$$

A homogeneous, stationary time series can be arrived at by appropriately differencing a homogeneous, nonstationary time series (Box and Jenkins 1976, p. 85). Preliminary application of an appropriate

transformation followed by differencing of a series can enable model identification and parameter estimation in the class of homogeneous stationary autoregressive moving average models.

Fatal Errors

IMSLS_PERIODS_LT_ZERO	"period[#]" = #. All elements of "period" must be greater than 0.
IMSLS_ORDER_NEGATIVE	"order[#]" = #. All elements of "order" must be nonnegative.
IMSLS_Z_CONTAINS_NAN	"z[#]" = NaN; "z" can not contain missing values. There may be other elements of "z" that are equal to NaN.

box_cox_transform

Performs a forward or an inverse Box-Cox (power) transformation.

Synopsis

float `*imsls_f_box_cox_transform` (*int* `n_observations`, *float* `z[]`, *float* `power`, ..., 0)

The type *double* function is `imsls_d_box_cox_transform`.

Required Arguments

int `n_observations` (Input)
Number of observations in `z`.

float `z[]` (Input)
Array of length `n_observations` containing the observations.

float `power` (Input)
Exponent parameter in the Box-Cox (power) transformation.

Return Value

Pointer to an internally allocated array of length `n_observations` containing the transformed data. To release this space, use `imsls_free`. If no value can be computed, then `NULL` is returned.

Synopsis with Optional Arguments

```
float *imsls_f_box_cox_transform (int n_observations, float z[], float power,
        IMSLS_SHIFT, float shift,
        IMSLS_INVERSE_TRANSFORM,
        IMSLS_RETURN_USER, float x[],
        0)
```

Optional Arguments

`IMSLS_SHIFT`, *float* `shift` (Input)

Shift parameter in the Box-Cox (power) transformation. Parameter shift must satisfy the relation min ($z(i)$) + `shift` > 0.

Default: `shift` = 0.0.

`IMSLS_INVERSE_TRANSFORM`

If `IMSLS_INVERSE_TRANSFORM` is specified, the inverse transform is performed.

`IMSLS_RETURN_USER`, *float* `x[]` (Output)

User-allocated array of length `n_observations` containing the transformed data.

Description

Function `imsls_f_box_cox_transform` performs a forward or an inverse Box-Cox (power) transformation of n = `n_observations` observations $\{Zt\}$ for t = 1, 2, ..., n.

The forward transformation is useful in the analysis of linear models or models with nonnormal errors or nonconstant variance (Draper and Smith 1981, p. 222). In the time series setting, application of the appropriate transformation and subsequent differencing of a series can enable model identification and parameter estimation in the class of homogeneous stationary autoregressive-moving average models. The inverse transformation can later be applied to certain results of the analysis, such as forecasts and prediction limits of forecasts, in order to express the results in the scale of the original data. A brief note concerning the choice of transformations in the time series models is given in Box and Jenkins (1976, p. 328).

The class of power transformations discussed by Box and Cox (1964) is defined by

$$X_t = \begin{cases} \dfrac{(Z_t + \xi)^{\lambda} - 1}{\lambda} & \lambda \neq 0 \\ \ln(Z_t + \xi) & \lambda = 0 \end{cases}$$

where Zt + ξ > 0 for all t. Since

$$\lim_{\lambda \to 0} \frac{(Z_t + \xi)^{\lambda} - 1}{\lambda} = \ln(Z_t + \xi)$$

the family of power transformations is continuous.

Let λ = `power` and ξ = `shift`; then, the computational formula used by `imsls_f_box_cox_transform` is given by

$$X_t = \begin{cases} (Z_t + \xi)^{\lambda} & \lambda \neq 0 \\ \ln(Z_t + \xi) & \lambda = 0 \end{cases}$$

where Zt + ξ > 0 for all t. The computational and Box-Cox formulas differ only in the scale and origin of the transformed data. Consequently, the general analysis of the data is unaffected (Draper and Smith 1981, p. 225).

The inverse transformation is computed by

$$X_t = \begin{cases} Z_t^{1/\lambda} - \xi & \lambda \neq 0 \\ exp(Z_t) - \xi & \lambda = 0 \end{cases}$$

where {Zt} now represents the result computed by `imsls_f_box_cox_transform` for a forward transformation of the original data using parameters λ and ξ.

Fatal Errors

`IMSLS_ILLEGAL_SHIFT`	"shift" = # and the smallest element of "z" is "z[#]" = #. "shift" plus "z[#]" = #. "shift" + "z[i]" must be greater than 0 for i = 1, ..., "n_observations". "n_observations" = #.

IMSLS_BCTR_CONTAINS_NAN	One or more elements of “z” is equal to NaN (Not a number). No missing values are allowed. The smallest index of an element of “z” that is equal to NaN is #.
IMSLS_BCTR_F_UNDERFLOW	Forward transform. “power” = #. “shift” = #. The minimum element of “z” is “z[#]” = #. (“z[#]”+ “shift”) ^ “power” will underflow.
IMSLS_BCTR_F_OVERFLOW	Forward transformation. “power” = #. “shift” = #. The maximum element of “z” is “z[#]” = #. (“z[#]” + “shift”) ^ “power” will overflow.
IMSLS_BCTR_I_UNDERFLOW	Inverse transformation. “power” = #. The minimum element of “z” is “z[#]” = #. exp(“z[#]”) will underflow.
IMSLS_BCTR_I_OVERFLOW	Inverse transformation. “power” = #. The maximum element of “z[#]” = #. exp(“z[#]”) will overflow.
IMSLS_BCTR_I_ABS_UNDERFLOW	Inverse transformation. “power” = #. The element of “z” with the smallest absolute value is “z[#]” = #. “z[#]” ^ (1/ “power”) will underflow.
IMSLS_BCTR_I_ABS_OVERFLOW	Inverse transformation. “power” = #. The element of “z” with the largest absolute value is “z[#]” = #. “z[#]” ^ (1/ “power”) will overflow.

autocorrelation

Computes the sample autocorrelation function of a stationary time series.

Synopsis

float `*imsls_f_autocorrelation` (*int* `n_observations`, *float* `x[]`,
int `lagmax`, ...0)

The type *double* function is `imsls_d_autocorrelation`.

Required Arguments

int `n_observations` (Input)

Number of observations in the time series `x`. `n_observations` must be greater than or equal to 2.

float `x[]` (Input)

Array of length `n_observations` containing the time series.

int `lagmax` (Input)

Maximum lag of autocovariance, autocorrelations, and standard errors of autocorrelations to be computed. `lagmax` must be greater than or equal to 1 and less than `n_observations`.

Return Value

Pointer to an array of length `lagmax` + 1 containing the autocorrelations of the time series `x`. The *0*-th element of this array is 1. The *k*-th element of this array contains the autocorrelation of lag *k* where *k* = 1, ..., `lagmax`.

Synopsis with Optional Arguments

```
float *imsls_f_autocorrelation (int n_observations, float x[],
    int lagmax,
    IMSLS_PRINT_LEVEL, int iprint,
    IMSLS_X_MEAN_IN, float x_mean_in,
    IMSLS_X_MEAN_OUT, float *x_mean_out,
    IMSLS_ACV, float **autocovariances,
    IMSLS_ACV_USER, float autocovariances[],
    IMSLS_SEAC, float **standard_errors, int se_option,
    IMSLS_SEAC_USER, float standard_errors[], int se_option,
    IMSLS_RETURN_USER, float autocorrelations[],
    0)
```

Optional Arguments

`IMSLS_PRINT_LEVEL`, *int* `iprint` (Input)

Printing option.

Default = 0.

Iprint	Action
0	No printing is performed.
1	Prints the mean and variance.
2	Prints the mean, variance, and autocovariances.
3	Prints the mean, variance, autocovariances, autocorrelations, and standard errors of autocorrelations.

IMSLS_X_MEAN_IN, *float* x_mean_in (Input)

User input the estimate of the time series x.

IMSLS_X_MEAN_OUT, *float* *x_mean_out (Output)

If specified, x_mean_out is the estimate of the mean of the time series x.

IMSLS_ACV, *float* **autocovariances (Output)

Address of a pointer to an array of length lagmax + 1 containing the variance and autocovariances of the time series x. The *0*-th element of this array is the variance of the time series x. The *k*th element contains the autocovariance of lag *k* where *k* = 1, ..., lagmax.

IMSLS_ACV_USER, *float* autocovariances[] (Output)

If specified, autocovariances is an array of length lagmax + 1 containing the variance and autocovariances of the time series x.

IMSLS_SEAC, *float* **standard_errors, *int* se_option (Output)

Address of a pointer to an array of length lagmax containing the standard errors of the autocorrelations of the time series x.

Method of computation for standard errors of the autocorrelations is chosen by se_option.

se_option	Action
1	Compute the standard errors of autocorrelations using Barlett's formula.
2	Compute the standard errors of autocorrelations using Moran's formula.

IMSLS_SEAC_USER, *float* standard_errors[], *int* se_option (Output)

If specified, autocovariances is an array of length lagmax containing the standard errors of the autocorrelations of the time series x.

IMSLS_RETURN_USER, *float* autocorrelations[] (Output)

If specified, autocorrelations is an array of length lagmax + 1 containing the autocorrelations of the time series x. The *o*th element of this array is 1. The *k*th element of this array contains the autocorrelation of lag k where k = 1, ..., lagmax.

Description

Function imsls_f_autocorrelation estimates the autocorrelation function of a stationary time series given a sample of n = n_observations observations {*X*t} for t = 1, 2, …, n.

Let

$$\hat{\mu} = \text{x mean}$$

be the estimate of the mean μ of the time series {*X*t} where

$$\hat{\mu} = \begin{cases} \mu, & \mu \text{ known} \\ \dfrac{1}{n}\displaystyle\sum_{t=1}^{n} X_t & \mu \text{ unknown} \end{cases}$$

The autocovariance function σ(k) is estimated by

$$\hat{\sigma}(k) = \frac{1}{n}\sum_{t=1}^{n-k}(X_t - \hat{\mu})(X_{t+k} - \hat{\mu}), \quad k = 0,1,\ldots, K$$

where K = lagmax. Note that

$$\hat{\sigma}(0)$$

is an estimate of the sample variance. The autocorrelation function ρ(*k*) is estimated by

$$\hat{\rho}(k) = \frac{\hat{\sigma}(k)}{\hat{\sigma}(0)}, \qquad k = 0,1,\ldots, K$$

Note that

$$\hat{\rho}(0) \equiv 1$$

by definition.

The standard errors of the sample autocorrelations may be optionally computed according to argument `se_option` for the optional argument `IMSLS_SEAC`. One method (Bartlett 1946) is based on a general asymptotic expression for the variance of the sample autocorrelation coefficient of a stationary time series with independent, identically distributed normal errors. The theoretical formula is

$$\text{var}\{\hat{\rho}(\text{k})\} = \frac{1}{n}\sum_{i=-\infty}^{\infty}\left[\rho^2(i) + \rho(i-k)\rho(i+k) - 4\rho(i)\rho(k)\rho(i-k) + 2\rho^2(i)\rho^2(k)\right]$$

where

$$\hat{\rho}(k)$$

assumes μ is unknown. For computational purposes, the autocorrelations r(k) are replaced by their estimates

$$\hat{\rho}(k)$$

for $|k| \leq K$, and the limits of summation are bounded because of the assumption that r(k) = 0 for all k such that $|k| > K$.

A second method (Moran 1947) utilizes an exact formula for the variance of the sample autocorrelation coefficient of a random process with independent, identically distributed normal errors. The theoretical formula is

$$\text{var}\left\{\hat{\rho}(k)\right\} = \frac{n-k}{n(n+2)}$$

where μ is assumed to be equal to zero. Note that this formula does not depend on the autocorrelation function.

partial_autocorrelation

Computes the sample partial autocorrelation function of a stationary time series.

Synopsis

float `*imsls_f_partial_autocorrelation` (*int* `lagmax`, *int* `cf[]`, …, 0)

The type *double* function is `imsls_d_partial_autocorrelation`.

Required Arguments

int `lagmax` (Input)
Maximum lag of partial autocorrelations to be computed.

float `cf[]` (Input)
Array of length `lagmax + 1` containing the autocorrelations of the time series `x`.

Return Value

Pointer to an array of length `lagmax` containing the partial autocorrelations of the time series `x`.

Synopsis with Optional Arguments

float `*imsls_f_partial_autocorrelation` (*int* `lagmax`, *float* `cf[]`,
`IMSLS_RETURN_USER`, *float* `partial_autocorrelations[]`,
0)

Optional Arguments

`IMSLS_RETURN_USER`, *float* `partial_autocorrelations[]` (Output)

If specified, the partial autocorrelations are stored in an array of length `lagmax` provided by the user.

Description

Function `imsls_f_partial_autocorrelation` estimates the partial autocorrelations of a stationary time series given the *K* = `lagmax` sample autocorrelations

$$\hat{\rho}(k)$$

for *k* = 0, 1, …, *K*. Consider the AR(*k*) process defined by

$$X_t = \phi_{k1} X_{t-1} + \phi_{k2} X_{t-2} + \ldots + \phi_{kk} X_{t-k} + A_t$$

where ϕkj denotes the *j*-th coefficient in the process. The set of estimates

$$\left\{\hat{\phi}_{kk}\right\}$$

for *k* = 1, …, *K* is the sample partial autocorrelation function. The autoregressive parameters

$$\left\{\hat{\phi}_{kj}\right\}$$

for *j* = 1, …, *k* are approximated by Yule-Walker estimates for successive AR(*k*) models where *k* = 1, …, *K*. Based on the sample Yule-Walker equations

$$\hat{\rho}(j) = \hat{\phi}_{k1}\hat{\rho}(j-1) + \hat{\phi}_{k2}\hat{\rho}(j-2) + \ldots + \hat{\phi}_{kk}\hat{\rho}(j-k), \quad j = 1, 2, \ldots, k$$

a recursive relationship for *k* = 1, …, *K* was developed by Durbin (1960). The equations are given by

$$\hat{\phi}_{kk} = \begin{cases} \hat{\rho}(1) & k = 1 \\ \dfrac{\hat{\rho}(k) - \sum_{j=1}^{k-1} \hat{\phi}_{k-1,j}\hat{\rho}(k-j)}{1 - \sum_{j=1}^{k-1} \hat{\phi}_{k-1,j}\hat{\rho}(j)} & k = 2, \ldots, K \end{cases}$$

and

$$\hat{\phi}_{kk} = \begin{cases} \hat{\rho}(1) & k = 1 \\ \dfrac{\hat{\rho}(k) - \sum_{j=1}^{k-1} \hat{\phi}_{k-1,j}\hat{\rho}(k-j)}{1 - \sum_{j=1}^{k-1} \hat{\phi}_{k-1,j}\hat{\rho}(j)} & k = 2, \ldots, K \end{cases}$$

This procedure is sensitive to rounding error and should not be used if the parameters are near the nonstationarity boundary. A possible alternative would be to estimate {ϕkk} for successive AR(*k*) models using least or maximum likelihood. Based on the hypothesis that the true process is AR(*p*), Box and Jenkins (1976, page 65) note

$$\text{var}\{\hat{\phi}_{kk}\} \simeq \frac{1}{n} \quad k \geq p+1$$

See Box and Jenkins (1976, pages 82–84) for more information concerning the partial autocorrelation function.

lack_of_fit

Performs lack-of-fit test for a univariate time series or transfer function given the appropriate correlation function.

Synopsis

float `*imsls_lack_of_fit` (*int* `n_observations`, *float* `cf[]`,
int `lagmax`, *int* `npfree`,..., 0)

Required Arguments

int `n_observations` (Input)
Number of observations of the stationary time series.

float `cf[]` (Input)
Array of length `lagmax`+1 containing the correlation function.

int `lagmax` (Input)

Maximum lag of the correlation function.

int `npfree` (Input)

Number of free parameters in the formulation of the time series model. `npfree` must be greater than or equal to zero and less than `lagmax`. Woodfield (1990) recommends `npfree = p + q`.

Return Value

Pointer to an array of length 2 with the test statistic, Q, and its *p*-value, *p*. Under the null hypothesis, Q has an approximate chi-squared distribution with `lagmax-lagmin+1-npfree` degrees of freedom.

Synopsis with Optional Arguments

```
#include <imsls.h>

float *imsls_f_lack_of_fit (int n_observations, float cf[], int lagmax,
        int npfree,
        IMSLS_LAGMIN, int lagmin,
        IMSLS_RETURN_USER, float stat[],
        0)
```

Optional Arguments

`IMSLS_LAGMIN`, *int* `lagmin` (Input)

Minimum lag of the correlation function. `lagmin` corresponds to the lower bound of summation in the lack of fit test statistic. Default value is 1.

`IMSLS_RETURN_USER`, *float* `stat[]` (Output)

User defined array for storage of lack-of-fit statistics.

Description

Routine `imsls_f_lack_of_fit` may be used to diagnose lack of fit in both ARMA and transfer function models. Typical arguments for these situations are:

Model	LAGMIN	LAGMAX	NPFREE
ARMA (*p, q*)	1	$\sqrt{\text{NOBS}}$	$p + q$
Transfer function	0	$\sqrt{\text{NOBS}}$	$r + s$

Function `imsls_f_lack_of_fit` performs a portmanteau lack of fit test for a time series or transfer function containing `n` observations given the appropriate sample correlation function

$$\hat{\rho}(k)$$

for $k = L, L + 1, \ldots, K$ where L = `lagmin` and K = `lagmax`.

The basic form of the test statistic Q is

$$Q = n(n+2)\sum_{k=L}^{K}(n-k)^{-1}\hat{\rho}(k)$$

with $L = 1$ if

$$\hat{\rho}(k)$$

is an autocorrelation function. Given that the model is adequate, Q has a chi-squared distribution with $K - L + 1 - m$ degrees of freedom where m = `npfree` is the number of parameters estimated in the model. If the mean of the time series is estimated, Woodfield (1990) recommends not including this in the count of the parameters estimated in the model. Thus, for an ARMA(p, q) model set `npfree`= $p + q$ regardless of whether the mean is estimated or not. The original derivation for time series models is due to Box and Pierce (1970) with the above modified version discussed by Ljung and Box (1978). The extension of the test to transfer function models is discussed by Box and Jenkins (1976, pages 394–395).

estimate_missing

Estimates missing values in a time series.

Synopsis

float `*imsls_f_estimate_missing`(*int* `n_obs`, *int* `tpoints[]`,
float `z[]`, …, 0)

The type *double* function is `imsls_d_estimate_missing`.

Required Arguments

int `n_obs` (Input)

Number of non-missing observations in the time series. The time series must not contain gaps with more than 3 missing values.

int `tpoints[]` (Input)

Vector of length `n_obs` containing the time points $t_1, \ldots, t_{n\_obs}$ at which the time series values were observed. The time points must be in strictly increasing order. Time points for missing values must lie in the open interval (t_1, t_{n_obs}).

float `z[]` (Input)

Vector of length `n_obs` containing the time series values. The values must be ordered in accordance with the values in vector `tpoints`. It is assumed that the time series after estimation of missing values contains values at equidistant time points where the distance between two consecutive time points is one. If the non-missing time series values are observed at time points $t_1, \ldots, t_{n\_obs}$, then missing values between t_i and t_{i+1}, $i = 1, \ldots, \texttt{n\_obs} - 1$, exist if $t_{i+1} - t_i > 1$. The size of the gap between t_i and t_{i+1} is then $t_{i+1} - t_i - 1$. The total length of the time series with non-missing and estimated missing values is $t_{n\_obs} - t_1 + 1$, or `tpoints[n_obs-1]-tpoints[0]+1`.

Return Value

Pointer to an array of length (`tpoints[n_obs-1]-tpoints[0]+1`) containing the time series together with estimates for the missing values. If an error occurred, `NULL` is returned.

Synopsis with Optional Arguments

```
float   *imsls_f_estimate_missing (int n_obs, int tpoints[], float z[],
        IMSLS_METHOD, int method,
        IMSLS_MAX_LAG, int maxlag,
        IMSLS_NTIMES, int *ntimes,
        IMSLS_MEAN_ESTIMATE, float mean_estimate,
        IMSLS_CONVERGENCE_TOLERANCE, float convergence_tolerance,
        IMSLS_RELATIVE_ERROR, float relative_error,
        IMSLS_MAX_ITERATIONS, int max_iterations,
        IMSLS_TIMES_ARRAY, int **times,
        IMSLS_TIMES_ARRAY_USER,  int times[],
        IMSLS_MISSING_INDEX, int **missing_index,
        IMSLS_MISSING_INDEX_USER, int missing_index[],
        IMSLS_RETURN_USER, float u_z[],
        0)
```

Optional Arguments

IMSLS_METHOD, *int* method (Input)

The method used for estimating the missing values:

0 — Use median.
1 — Use cubic spline interpolation.
2 — Use one-step-ahead forecasts from an AR(1) model.
3 — Use one-step-ahead forecasts from an AR(p) model.

Default: method = 3

If method = 2 is chosen, then all values of gaps beginning at time points t_1+1 or t_1+2 are estimated by method 0. If method = 3 is chosen and the first gap starts at t_1+1, then the values of this gap are also estimated by method 0. If the length of the series before a gap, denoted len, is greater than 1 and less than $2 \cdot$ maxlag, then maxlag is reduced to len/2 for the computation of the missing values within this gap.

IMSLS_MAX_LAG, *int* maxlag (Input)

Maximum lag number when method = 3 was chosen.

Default: maxlag = 10

IMSLS_NTIMES, *int* *ntimes (Output)

Number of elements in the time series with estimated missing values. Note that ntimes = tpoints[n_obs-1]-tpoints[0]+1.

IMSLS_MEAN_ESTIMATE, *float* mean_estimate (Input)

Estimate of the mean of the time series.

IMSLS_CONVERGENCE_TOLERANCE, *float* convergence_tolerance (Input)

Tolerance level used to determine convergence of the nonlinear least squares algorithm used in method 2. Argument convergence_tolerance represents the minimum relative decrease in the sum of squares between two iterations required to determine convergence. Hence, convergence_tolerance must be greater than or equal to 0.

Default: $\max\{10^{-10}, \text{eps}^{2/3}\}$ for single precision and $\max\{10^{-20}, \text{eps}^{2/3}\}$ for double precision, where eps =imsls_f_machine(4) for single precision and eps =imsls_d_machine(4) for double precision.

IMSLS_RELATIVE_ERROR, *float* relative_error (Input)

Stopping criterion for use in the nonlinear equation solver used by method 2.

Default: relative_error = 100 × imsls_f_machine(4) for single precision, relative_error = 100 × imsls_d_machine(4) for double precision..

IMSLS_MAX_ITERATIONS, *int* max_iterations (Input)

Maximum number of iterations allowed in the nonlinear equations solver used by method 2.

Default: max_iterations = 200.

IMSLS_TIMES_ARRAY, *int* **times (Output)

Address of a pointer to an internally allocated array of length ntimes = tpoints[n_obs-1]-tpoints[0]+1 containing the time points of the time series with estimates for the missing values.

IMSLS_TIMES_ARRAY_USER, *int* times[] (Output)

Storage for array times is provided by the user. See IMSLS_TIMES_ARRAY.

IMSLS_MISSING_INDEX, *int* **missing_index (Output)

Address of a pointer to an internally allocated array of length (ntimes-n_obs) containing the indices for the missing values in array times. If ntimes-n_obs = 0, then no missing value could be found and NULL is returned.

IMSLS_MISSING_INDEX_USER, *int* missing_index[] (Output)

Storage for array missing_index is provided by the user. See IMSLS_MISSING_INDEX.

IMSLS_RETURN_USER, *float* u_z[] (Output)

If specified, u_z is a vector of length tpoints[n_obs-1]-tpoints[0]+1 containing the time series values together with estimates for missing values.

Description

Traditional time series analysis as described by Box, Jenkins and Reinsel (1994) requires the observations made at equidistant time points $t_1, t_1+1, t_1+2, \ldots, t_n$. When observations are missing, the problem occurs to determine suitable estimates. Function imsls_f_estimate_missing offers 4 estimation methods:

Method 0 estimates the missing observations in a gap by the median of the last four time series values before and the first four values after the gap. If not enough values are available before or after the gap then the number is reduced accordingly. This method is very fast and simple, but its use is limited to stationary ergodic series without outliers and level shifts.

Method 1 uses a cubic spline interpolation method to estimate missing values. Here the interpolation is again done over the last four time series values before and the first four values after the gap. The missing values are estimated by the resulting interpolant. This method gives smooth transitions across missing values.

Method 2 assumes that the time series before the gap can be well described by an AR(1) process. If the last observation prior to the gap is made at time point t_m then it uses the time series values at $t_1, t_1+1, \ldots, t_m$ to compute the one-step-ahead forecast at origin t_m. This value is taken as an estimate for the missing value at time point t_{m+1}. If the value at t_{m+1} is also missing then the values at time points $t_1, t_1+1, \ldots, t_{m+1}$ are used to recompute the AR(1) model, estimate the value at t_{m+2} and so on. The coefficient ϕ_1 in the AR(1) model is computed internally by the method of least squares from routine imsls_f_arma.

Finally, method 3 uses an AR(p) model to estimate missing values by a one-step-ahead forecast . First, function imsls_f_auto_uni_ar, applied to the time series prior to the missing values, is used to determine the optimum p from the set {0, 1, …, max_lag} of possible values and to compute the parameters $\phi_1, \ldots, \phi_p$ of the resulting AR(p) model. The parameters are estimated by the least squares

method based on Householder transformations as described in Kitagawa and Akaike (1978). Denoting the mean of the series $y_{t_1}, y_{t_1+1}, \ldots, y_{t_m}$ by μ the one-step-ahead forecast at origin t_m, $\hat{y}_{t_m}(1)$, can be computed by the formula

$$\hat{y}_{t_m}(1) = \mu(1 - \sum_{j=1}^{p} \phi_j) + \sum_{j=1}^{p} \phi_j y_{t_m+1-j} \ .$$

This value is used as an estimate for the missing value. The procedure starting with imsls_f_auto_uni_ar is then repeated for every further missing value in the gap. All four estimation methods treat gaps of missing values in increasing time order.

garch

Computes estimates of the parameters of a GARCH(*p*,*q*) model.

Synopsis

float `*imsls_f_garch` (*int* `p`, *int* `q`, *int* `m`, *float* `y[]`, *float* `xguess[]`, …, 0)

The type *double* function is `imsls_d_garch`.

Required Arguments

int `p` (Input)
Number of GARCH parameters.

int `q` (Input)
Number of ARCH parameters.

int `m` (Input)
Length of the observed time series.

float `y[]` (Input)
Array of length `m` containing the observed time series data.

float `xguess[]` (Input)
Array of length `p` + `q` + 1 containing the initial values for the parameter array `x[]`.

Return Value

Pointer to the parameter array `x[]` of length `p` + `q` + 1 containing the estimated values of sigma squared, followed by the `q` ARCH parameters, and the `p` GARCH parameters.

Synopsis with Optional Arguments

```
float *imsls_f_garch (int p, int q, int m, float y[], float xguess[],
        IMSLS_MAX_SIGMA, float max_sigma,
        IMSLS_A, float *a,
        IMSLS_AIC, float *aic,
        IMSLS_RETURN_USER, float x[],
        0)
```

Optional Arguments

`IMSLS_MAX_SIGMA`, *float* `max_sigma`, (Input)
Value of the upperbound on the first element (sigma) of the array of returned estimated coefficients. Default = 10.

`IMSLS_A`, *float* *`a`, (Output)
Value of Log-likelihood function evaluated at the estimated parameter array x.

`IMSLS_AIC`, *float* *`aic`, (Output)
Value of Akaike Information Criterion evaluated at the estimated parameter array x.

`IMSLS_RETURN_USER`, *float* `x[]`, (Output)
If specified, x returns an array of length $p + q + 1$ containing the estimated values of sigma squared, followed by the q ARCH parameters, and the p GARCH parameters. Storage for estimated parameter array x is provided by the user.

Description

The Generalized Autoregressive Conditional Heteroskedastic (GARCH) model for a time series $\{w_t\}$ is defined as

$$w_t = z_t \sigma_t$$
$$\sigma_t^2 = \sigma^2 + \sum_{i=1}^{p} \beta_i \sigma_{t-i}^2 + \sum_{i=1}^{q} \alpha_i w_{t-i}^2,$$

where z_t's are independent and identically distributed standard normal random variables,

$$0 < \sigma^2 < \texttt{max\_sigma},\ \beta_i \geq 0,\ \alpha_i \geq 0 \text{ and}$$
$$\sum_{i=2}^{p+q+1} x(i) = \sum_{i=1}^{p} \beta_i + \sum_{i=1}^{q} \alpha_i < 1.$$

The above model is denoted as GARCH(p,q). The β_i and α_i coeffecients will be referred to as GARCH and ARCH coefficents, respectively. When $\beta_i = 0$, $i = 1,2,\ldots,p$, the above model reduces to ARCH(q) which was proposed by Engle (1982). The nonnegativity conditions on the parameters imply a nonnegative variance and the condition on the sum of the β_i's and α_i's is required for wide sense stationarity.

In the empirical analysis of observed data, GARCH(1,1) or GARCH(1,2) models have often found to appropriately account for conditional heteroskedasticity (Palm 1996). This finding is similar to linear time series analysis based on ARMA models.

It is important to notice that for the above models positive and negative past values have a symmetric impact on the conditional variance. In practice, many series may have strong asymmetric influence on the conditional variance. To take into account this phenomena, Nelson (1991) put forward Exponential GARCH (EGARCH). Lai (1998) proposed and studied some properties of a general class of models that extended linear relationship of the conditional variance in ARCH and GARCH into nonlinear fashion.

The maximum likelihood method is used in estimating the parameters in GARCH(p,q). The log-likelihood of the model for the observed series $\{w_t\}$ with length m = `nobs` is

$$\log(L) = -\frac{m}{2}\log(2\pi) - \frac{1}{2}\sum_{t=1}^{m} y_t^2 / \sigma_t^2 - \frac{1}{2}\sum_{t=1}^{m}\log\sigma_t^2,$$

$$\textit{where } \sigma_t^2 = \sigma^2 + \sum_{i=1}^{p}\beta_i\sigma_{t-i}^2 + \sum_{i=1}^{q}\alpha_i w_{t-i}^2.$$

Thus log(L) is maximized subject to the constraints on the α_i, β_i, and σ.

In this model, if q = 0, the GARCH model is singular since the estimated Hessian matrix is singular.

The initial values of the parameter vector `x` entered in vector `xguess` must satisfy certain constraints. The first element of `xguess` refers to σ^2 and must be greater than zero and less than `max_sigma`. The remaining p+q initial values must each be greater than or equal to zero and sum to a value less than one.

To guarantee stationarity in model fitting,

$$\sum_{i=2}^{p+q+1} x(i) = \sum_{i=1}^{p}\beta_i + \sum_{i=1}^{q}\alpha_i < 1$$

is checked internally. The initial values should selected from values between zero and one.

`AIC` is computed by

$$-2\log(L) + 2(p+q+1),$$

where log(L) is the value of the log-likelihood function.

Statistical inferences can be performed outside the routine `GARCH` based on the output of the log-likelihood function `(A)`, the Akaike Information Criterion (AIC), and the variance-covariance matrix `(VAR)`.

Reference Material

User Errors

IMSL functions attempt to detect user errors and handle them in a way that provides as much information to the user as possible. To do this, various levels of severity of errors are recognized, and the extent of the error in the context of the purpose of the function also is considered; a trivial error in one situation can be serious in another. IMSL attempts to report as many errors as can reasonably be detected. Multiple errors present a difficult problem in error detection because input is interpreted in an uncertain context after the first error is detected.

What Determines Error Severity

In some cases, the user's input may be mathematically correct, but because of limitations of the computer arithmetic and of the algorithm used, it is not possible to compute an answer accurately. In this case, the assessed degree of accuracy determines the severity of the error. In cases where the function computes several output quantities, some are not computable but most are, an error condition exists. The severity of the error depends on an assessment of the overall impact of the error.

Kinds of Errors and Default Actions

Five levels of severity of errors are defined in IMSL C/Stat/Library. Each level has an associated PRINT attribute and a STOP attribute. These attributes have default settings (YES or NO), but they may also be set by the user. The purpose of having multiple error types is to provide independent control of actions to be taken for errors of different levels of severity. Upon return from an IMSL function, exactly one error state exists. (A code 0 "error" is no error.) Even if more than one informational error occurs, only one message is printed (if the PRINT attribute is YES). Multiple errors for which no corrective action within the calling program is reasonable or necessary result in the printing of multiple messages (if the PRINT attribute for their severity level is YES). Errors of any of the severity levels except `IMSLS_TERMINAL` may be informational errors. The include file, *imsls.h*, defines each of `IMSLS_NOTE`, `IMSLS_ALERT`, `IMSLS_WARNING`, `IMSLS_FATAL`, `IMSLS_TERMINAL`, `IMSLS_WARNING_IMMEDIATE`, and `IMSLS_FATAL_IMMEDIATE` as enumerated data type *Imsls_error*.

IMSLS_NOTE. A *note* is issued to indicate the possibility of a trivial error or simply to provide information about the computations.
Default attributes: PRINT=NO, STOP=NO

IMSLS_ALERT. An *alert* indicates that a function value has been set to 0 due to underflow.
Default attributes: PRINT=NO, STOP=NO

IMSLS_WARNING. A *warning* indicates the existence of a condition that may require corrective action by the user or calling function. A warning error may be issued because the results are accurate to only a few decimal places; because some of the output may be erroneous, but most of the output is correct; or because some assumptions underlying the analysis technique are violated. Usually no corrective action is necessary, and the condition can be ignored.
Default attributes: PRINT=YES, STOP=NO

IMSLS_FATAL. A *fatal* error indicates the existence of a condition that may be serious. In most cases, the user or calling function must take corrective action to recover.
Default attributes: PRINT=YES, STOP=YES

IMSLS_TERMINAL. A *terminal* error is serious. It usually is the result of an incorrect specification, such as specifying a negative number as the number of equations. These errors can also be caused by various programming errors impossible to diagnose correctly in C. The resulting error message may be perplexing to the user. In such cases, the user is advised to compare carefully the actual arguments passed to the function with the dummy argument descriptions given in the documentation. Special attention should be given to checking argument order and data types.

A terminal error is not an informational error, because corrective action within the program is generally not reasonable. In normal use, execution is terminated immediately when a terminal error occurs. Messages relating to more than one terminal error are printed if they occur.
Default attributes: PRINT=YES, STOP=YES

IMSLS_WARNING_IMMEDIATE. An *immediate warning* error is identical to a warning error, except it is printed immediately.
Default attributes: PRINT=YES, STOP=NO

IMSLS_FATAL_IMMEDIATE. An *immediate fatal* error is identical to a fatal error, except it is printed immediately.
Default attributes: PRINT=YES, STOP=YES

The user can set PRINT and STOP attributes by calling function imsls_error_options.

Product Support

Contacting Visual Numerics Support

Users within support warranty may contact Visual Numerics regarding the use of the IMSL C Numerical Library. Visual Numerics can consult on the following topics:

- Clarity of documentation
- Possible Visual Numerics-related programming problems
- Choice of IMSL Libraries functions or procedures for a particular problem

Not included in these topics are mathematical/statistical consulting and debugging of your program.

Refer to the following for Visual Numerics Product Support contact information:

- http://www.vni.com/tech/imsl/phone.php

The following describes the procedure for consultation with Visual Numerics:

1. Include your Visual Numerics license number
2. Include the product name and version number: IMSL C Numerical Library Version 7.0
3. Include compiler and operating system version numbers
4. Include the name of the routine for which assistance is needed and a description of the problem

Schmeiser, Bruce W. and Ram Lal (1980), Squeeze methods for generating gamma variates, *Journal of the American Statistical Association*, **75**, 679–682.

Searle

Searle, S.R. (1971), *Linear Models*, John Wiley & Sons, New York.

Seber

Seber, G.A.F. (1984), *Multivariate Observations*, John Wiley & Sons, New York.

Snedecor and Cochran

Snedecor and Cochran (1967) *Statistical Methods*, 6th edition, Iowa State University Press.

Snedecor and Cochran

Snedecor, George W. and Cochran, William G. (1967) *Statistical Methods*, 6th edition, Iowa State University Press, 296-298.

Snedecor, George W. and Cochran, William G. (1967) *Statistical Methods*, 6th edition, Iowa State University Press, 432－436.

Shampine

Shampine, L.F. (1975), Discrete least-squares polynomial fits, *Communications of the ACM*, **18**, 179–180.

Siegal

Siegal, Sidney (1956), *Nonparametric Statistics for the Behavioral Sciences*, McGraw-Hill, New York.

Singleton

Singleton, R.C. (1969), Algorithm 347: An efficient algorithm for sorting with minimal storage, *Communications of the ACM*, **12**, 185–187.

Smirnov

Smirnov, N.V. (1939), Estimate of deviation between empirical distribution functions in two independent samples (in Russian), *Bulletin of Moscow University*, **2**, 3–16.

Smith and Dubey

Smith, H., and S. D. Dubey (1964), "Some reliability problems in the chemical industry", Industrial Quality Control, 21 (2), 1964, 64-70.

Smith

Smith, M. (1993) *Neural Networks for Statistical Modeling*, New York: Van Nostrand Reinhold.

Snedecor and Cochran

Snedecor, George W. and William G. Cochran (1967), *Statistical Methods*, 6th ed., Iowa State University Press, Ames, Iowa.

Sposito

Sposito, Vincent A. (1989), Some properties of L_p-estimators, in *Robust Regression*: *Analysis and Applications* (edited by Kenneth D. Lawrence and Jeffrey L. Arthur), Marcel Dekker, New York, 23－58.

Spurrier and Isham

Spurrier, John D. and Steven P. Isham (1985), Exact simultaneous confidence intervals for pairwise comparisons of three normal means, *Journal of the American Statistical Association*, **80**, 438–442.

Stablein, Carter, and Novak

Stablein, D.M, W.H. Carter, and J.W. Novak (1981), Analysis of survival data with nonproportional hazard functions, *Controlled Clinical Trials*, **2**, 149–159.

Stahel

Stahel, W. (1981), Robuste Schatzugen: Infinitesimale Opimalitat und Schatzugen von Kovarianzmatrizen, Dissertation no. 6881, ETH, Zurich.

Steel and Torrie

Steel and Torrie (1960) *Principles and Procedures of Statistics*, McGraw-Hill.

Stephens

Stephens, M.A. (1974), EDF statistics for goodness of fit and some comparisons, *Journal of the American Statistical Association*, **69**, 730–737.

Stirling

Stirling, W.D. (1981), Least squares subject to linear constraints, *Applied Statistics*, **30**, 204–212. (See correction, p. 357.)

Stoline

Stoline, Michael R. (1981), The status of multiple comparisons: simultaneous estimation of all pairwise comparisons in one-way ANOVA designs,
The American Statistician, **35**, 134–141.

Strecok

Strecok, Anthony J. (1968), On the calculation of the inverse of the error function, *Mathematics of Computation*, **22**, 144–158.

Studenmund

Studenmund, A. H. (1992) Using Economics: A Practical Guide, New York: Harper Collins.

Swingler

Swingler, K. (1996) Applying Neural Networks: A Practical Guide, Academic Press.

Tanner and Wong

Tanner, Martin A., and Wing H. Wong (1983), The estimation of the hazard function from randomly censored data by the kernel method, *Annals of Statistics*, **11**, 989–993.

Tanner, Martin A., and Wing H. Wong (1984), Data-based nonparametric estimation of the hazard function with applications to model diagnostics and exploratory analysis, *Journal of the American Statistical Association*, **79**, 123–456.

Taylor and Thompson

Taylor, Malcolm S., and James R. Thompson (1986), Data based random number generation for a multivariate distribution via stochastic simulation, *Computational Statistics & Data Analysis*, **4**, 93−101.

Tesauro

Tesauro, G. (1990) Neurogammon Wins Computer Olympiad, *Neural Computation*, 1, 321-323.

Tezuka

Tezuka, S. (1995), *Uniform Random Numbers: Theory and Practice*. Academic Publishers, Boston.

Thompson

Thompson, James R, (1989), *Empirical Model Building*, John Wiley & Sons, New York.

Tong

Tong, Y. L. (1990), *The Multivariate Normal Distribution*, Springer-Verlag, New York.

Tucker and Lewis

Tucker, Ledyard and Charles Lewis (1973), A reliability coefficient for maximum likelihood factor analysis, *Psychometrika*, **38**, 1−10.

Tukey

Tukey, John W. (1962), The future of data analysis, *Annals of Mathematical Statistics,* **33**, 1−67.

Velleman and Hoaglin

Velleman, Paul F. and David C. Hoaglin (1981), *Applications, Basics, and Computing of Exploratory Data Analysis*, Duxbury Press, Boston.

Verdooren

Verdooren, L. R. (1963), Extended tables of critical values for Wilcoxon's test statistic, *Biometrika*, **50**, 177–186.

Wallace

Wallace, D.L. (1959), Simplified Beta-approximations to the Kruskal-Wallis H-test, *Journal of the American Statistical Association*, **54**, 225–230.

Warner

Warner, B. and Misra, M. (1996) Understanding Neural Networks as Statistical Tools, *The American Statistician*, 50(4) 284-293.

Weisberg
